Mr. Pearson thought that in view of what Mr. Gordon said, it would be better to defer further discussion on the matter until he read the paper referred to.

Mr. Wickson then said that it had occurred to him when listening to the very practical address delivered by the President, that if portions of it could be printed and distributed among the members of the Legislative Assembly, it would provide them in a very concise and lucid form a view of the whole question.

The President replied that the matter of legislation was one on which he felt very strongly, and he desired to have a full discussion in regard to it.

Mr. A. E. Paull, in expressing his concurrence in Mr. Wickson's suggestion, said that the President in his address had dealt with the various matters in a very able and admirable manner, particularly in that part in which he dealt with the advantages of architectural education. If not out of place he would move that copies of the President's address be sent to every member of the Legislature.

Mr. Wickson said that a suggestion just made to him by Mr. Gregg seemed to him a good one, viz : that a resolution be passed by the convention to the effect that in the address in question the President voiced the feeling of the Association. The resolution need not necessarily be sent to the members of the Legislature, but it would be reported in the newspapers, and they would see it there.

The President said that a great deal remained to be done before the matter could be dealt with satisfactorily. The action taken in the future would have to be more systematic. In regard to the proposition made, papers sent to the members of the Legislature were not often read, because they were overwhelmed with that kind of stuff. The best way of getting at the members was by having them personally interviewed while at their homes by the members of the Association living in their constituencies. This could not be effected unless the members of the Association took an interest in the matter and were willing to exert themselves. The volume of work to be done was not great, but what was to be done was important. When members of the Legislature came down to Toronto during the session they were very busy, and had any number of men trying to get at them in the interests of various legislation, and they had neither the time nor the inclination to talk, and even when they were spoken to they were apt to soon forget all about what they had heard. But in the country an architect, knowing the member for his district, if he could get hold of him for a short time, could do more than could be effected by any amount of work in Toronto. It was the country members of the Association who must be relied on. The city members he felt sure would do all in their power, but as far as the city members of the Legislature were concerned they were favorably disposed to the objects of the Association.

Mr. Wickson suggested that in addition to sending the proposed copies to the members of the Legislature they should also be sent to each member of the Association.

The President assented to that view, and suggested the formation of a small committee for the purpose of distributing this literature. There had appeared in the CANADIAN ARCHITECT AND BUILDER from time to time articles, portions of which would be valuable, and such a committee might arrange the matter.

Mr. Townsend thought that if members of the Association living in the country would address personal letters to the members of the Legislature in their constituencies, enclosing the proposed matter, it would be more effective than if sent from a central committee in Toronto. Country members might also enlist the sympathy and influence of friends outside the profession who had influence with the members of the Legislature. Indeed, he thought there was hardly a member of the Association in the city who had not a friend somewhere outside who might favorably influence some one.

The President thought Mr. Townsend's last suggestion was a very valuable one. If there were no further suggestions he would now proceed to the appointment of the committee.

Mr. Townsend recommended that the President's address be printed and distributed without mutilation ; he thought selections from it were not sufficient, but that it should be sent out in full.

Mr. Burke was of the same opinion. The main object was to show that the education of the architect was the legislation aimed at, and he thought the address would form an excellent argument for the desired legislation.

The following paper was then read by Mr. Gwynne :

SOME HINTS ON THE LEGAL RELATIONS BETWEEN ARCHITECT AND OWNER.

The first question that presents itself for consideration is the form of the contract between architect and client. Should it be reduced to writing? And the answer is, generally speaking, it need not. But there are two cases in which writing is essential. The first is where the services to be rendered are not to be completed within one year from the date of the contract. This is rendered necessary by the Statute of Frauds, an Act passed in the reign of Charles II, which requires many classes of contract to be evidenced by writing, and was passed as the preamble states, "for prevention of many fraudulent practices which are commonly endeavored to be upheld by perjury or subornation of perjury." The only point to be noted under this section of the Act is that the continuance of the services beyond the year must either be expressly provided by the terms of the contract, or be occasioned of necessity by the nature of the work ; if it may or may not be performed within the year no writing is required. There is a curious case in the early reports in illustration of this point. The defendant agreed with the plaintiff that he would give him 1,000 guineas on his wedding day, if the plaintiff would give him one guinea now. Two years afterwards the plaintiff married and claimed the 1,000 guineas. The defendant set up that the agreement not being performed within the year, could not be sued on as it was not evidenced by writing. But the judges held that the statute only

applied to agreements which are in their terms incapable of being performed within a year, and that there was nothing in the nature of the case before them to prevent the plaintiff marrying the next day. An architect, therefore, who is retained to superintend work which may be completed within the year, need not concern himself to have his retainer reduced to writing, but if by the terms of his agreement or from the nature of the work, his services are required for more than a year, he will not be able to recover his fees by action, unless the agreement upon which action shall be brought, or some memorandum or note thereof, shall be in writing and signed by the party to be charged therewith, or some other person thereunto by him lawfully authorized.

The other case in which writing is necessary is that of a contract with a corporation. It is a rule of the Common Law that a body corporate is not bound by any contract which is not under its corporate seal. There are two exceptions to this rule which I shall mention for the sake of completeness, although they are not likely to concern architects. Contracts with corporations in trivial matters of daily and pressing urgency need not be in writing or under seal, as for instance, the employment of servants, and secondly, in matters which are necessary and incidental to the express purposes for which incorporation was granted, particularly in the case of trading corporations.

To what extent corporations may plead the absence of a contract under seal, when sued, for work or service which they have ordered and accepted, is still a moot point, and was discussed in the Supreme Court as recently as the year 1891, with a very decided difference of opinion. Suffice it to say that in this province, the leaning, if not the law, is to hold corportions liable in such cases, but in England very eminent judges have expressed a contrary opinion. Under these circumstances it is but a wise precaution, to see in all cases of agreements with corporations, that the contract is reduced to writing and sealed.

But this is not the only question to be considered in making agreements with these bodies. We must enquire also whether the proposed contract comes within the scope of their powers, because if ultra vires, no recovery can be had against them notwithstanding that the contract is in writing and under seal, and the corporation has obtained the benefit of the work or services contracted for. To hold otherwise would be a virtual fraud on the shareholders who have subscribed on the faith of the corporation confining itself to the purposes for which it was created. If a company is incorporated for the manufacture of bicycles, it would be manifestly wrong to suffer its funds to be diverted to the operation of a railway.

In contracts with municipal corporations a still further precaution is necessary, for it has been decided that under the Ontario Municipal Act, contracts which have not been carried out, or to use more technical words, executory contracts, can not be enforced unless a by-law has been passed authorizing the contract, even though the seal has been affixed under a resolution of the Council. It would appear, therefore, to be necessary, when dealing with a municipal corporation, that an architect should not merely see that his agreement is under the corporate seal, but that a by-law has been duly passed authorizing the contract with him.

Before passing from this part of the subject, I shall quote the words of Baron Martin, "Persons dealing with those companies should always bear in mind that such companies are corporations, bodies essentially different from an ordinary partnership or firm, for all purposes of contract, and especially in respect of evidence against them on legal trials, and should insist upon these contracts being by deed under the seal of the company XXXXX. There is no safety or security for anyone dealing with such a body upon any other footing. The same observation also applies in respect of any variation or alteration in a contract which has been made."

These words apply with almost equal force to contracts with individuals, and should be borne in mind by every architect who, whether from delicacy or carelessness, neglects to have the agreement with his client reduced to writing, not merely to avoid lawsuits, but as a safe-guard against the misunderstanding which must almost inevitably arise, where the evidence on which contracts are to be established consists of loose and disconnected conversations between persons who are acting under possibly different assumptions.

These remarks are also a suitable prelude to the next question to be considered, as the difficulties which occur arise almost wholly from a failure to observe this necessary but generally neglected precaution. The question I allude to is, the architect's right to payment for his services, and here the difficulties we meet are great, but they arise not from any doubt as to the rules of law applicable, but from the difficulty of applying the rules to the vague and uncertain terms in which the parties are wont to make their agreements. When we remember that it is an almost daily occurrence to find the most conscientious men giving totally different versions of the same conversation or event, it need be no surprise to us if contracts for services which are to be arrived at from a few casual words, are difficult to ascertain with precision, especially when it is possible that one of the parties may have been quite content to leave his liability to inference, for the possible advantage he may thus subsequently hope to obtain. I refer, of course, only to verbal agreements; where the contract is reduced to writing, it is only a matter of construction. It will be well before proceeding to lay down the rules of law which have been formulated in regard to contracts of the nature of those which we are discussing. They are as follows:—

(1). No payment can be demanded for services rendered without request.

(2). If a person employs the services of another, without mention of payment, in matters for which payment is ordinarily expected, he impliedly undertakes to pay a reasonable sum.

(3). Where something is to be done as a condition precedent to a completed contract, no contractual rights or obligations arise until the condition is fulfilled.

(4). No claim can be based on services offered by way of tender, and no obligation arises on a call for services of a like nature.

These propositions you will say are sufficiently obvious, and as general propositions they no doubt are. The difficulty lies in their application. First, no payment can be demanded for services rendered without request. An architect calls on a gentleman who he hears contemplates building, and asks if he may prepare plans for him. The architect spends much time and trouble, and has special interviews with his client, who suggests alterations and evinces the interest usually shown in work done at one's expense; but on submitting the completed work, the architect learns to his chagrin, that his expected client has abandoned the idea of building. The latter swears that he had no idea that he was incurring liability, and the architect is equally emphatic that he had no intention of working for nothing. Under these facts, it is left to the jury to say whether there is a contract or whether it was a gratuitious offer of his services on the part of the architect without any request, and if they conclude it is the latter, no payment can be recovered. Architects would do well to remember that juries are apt to hold the views of the general public in regard to sketches and plans, that they are run off without any cost of time, thought, or trouble, and are of so small account in the eyes of their makers, that if not used, they do not expect to be paid for them, a view for which architects have in some measure themselves to blame, by reason of their readiness to tender their services in much the same manner as I have attempted to show. How then, is this danger to be avoided, a danger which is peculiarly incident to requests for plans? Simply by giving your client to understand that he is incurring liability. Leave nothing to inference and take nothing for granted."

The second proposition which I have laid down is, "If a person employs the services of another, without mention of payment, in matters for which payment is ordinarily expected, he impliedly undertakes to pay a reasonable sum."

The only point here which needs comment is the meaning to be attached to reasonable sum. This expression means neither 7% nor 5%, nor any other percentage, but such a sum as a jury can be induced to think the work reasonably worth. Of course other architects may be called as experts, to give evidence as to the charges usually made for the work in question, but no custom could be proved, that a certain percentage of the contract price of the building is the sum payable for the plans and another percentage for superintending. It may not be amiss to insert here a few words of caution on the question of customs, because I know that many of the architect's most cherished contentions are based on alleged customs. It is an undeniable rule that a custom or usage becomes a part of every contract, whether verbal or written, to which it is applicable, unless expressly excluded by the terms of the agreement. But a custom must be both certain and reasonable, and an unacknowledged one is by no means easy of proof. In cases of doubt is is a far safer plan to express the tegms which are sought to be relied on as a custom, rather than to rely on what laymen are often apt to call customs, where no custom is. As was said on one occasion by Lord Denman, "What can be more difficult than to ascertain, as a matter of fact, such a prevalence of what is called a custom of trade, as to justify a verdict that it forms part of every contract."

My third proposition is, "Where something is to be done as a condition precedent to a completed contract, no contractual rights or obligations arise until the condition is fulfilled." The difficulty here is again one of application; the whole point to determine being, do the words used amount to a condition precedent. The chief, if not the only application of the rule, of interest to Architects, arises where plans are called for, to be submitted for the approval of the owner. This is a matter of every day occurrence; in fact all plans are submitted for approval, but if the approval is a condition precedent, there can be no recovery without the approval, no matter how unreasonable the refusal may be, provided it is based on an exercise of judgment, and not the outcome of mere caprice. But if, on the other hand, there is an order for plans, although subject to the owner's approval, (in the sense that you can not compel him to build a house of which he does not approve the plan and design), in this case the owner will have to pay a proper sum for the work and services, even if he reject the plans, provided they are such as a reasonable man ought to accept upon the instructions given.

In the case which establishes this rule, the wording of the agreement was that the architect should prepare "the necessary probationary drawings for the approval of the committee of visitors," and this was held to mean drawings which shall be approved of by the Committee, and that the plans were not to be paid for unless approved of so as to become useful and available to the county.

If, therefore, trusting to your own ability to please and to your client's honor, you enter into an agreement to supply probationary drawings which shall be approved of by him, you may have all your work for nothing if you fail, and are liable to be dismissed if you do not succeed in a reasonable time. It must, however, be added that doubtful expressions will not be construed as conditions precedent, and the onus will be on the defendant to establish it. The ordinary instructions, therefore, for plans, will not come within the rule, but rather within the second rule, that where work is done at the request of another, if no mention is made of payment, he impliedly undertakes to pay a reasonable sum. There is an American case which aptly illustrates both the point we are discussing and the question of remuneration.

The plaintiffs sued for $170 being 1% of their own estimates. I quote the following expressions from the judgment: "Plaintiffs' theory seems to have been that by employing an architect to make drawings which are not finally determined on, and asking his opinion of probable cost, the employer is bound to pay a percentage on a building such as the architect sees fit to figure out, and at a price which he puts upon its probable cost."

This seems to us an idea which has no foundation in law or common sense and unless such a basis of compensation was specially agreed on, it cannot be allowed.

There is some reason for claiming that if a man is employed to make preliminary sketches, to enable a landowner to determine what sort of building he may profitably erect, in what style and of what material it should be built, he should not do the work without reward, provided such is the understanding. If, however, as the defendant here claimed, the architect volunteered his services with the chances of future employment, it would be different. But it cannot be held that in either case, such preliminary work can be measured by estimates of the cost of the architect's projected building. The only claim plaintiffs could have would be for such time as was actually spent in their work, with the fair understanding that they should be paid for so much as they did, or with such circumstances as would compel defendant to the duty of so understanding; but no custom of architects can be received to fix it on any such basis as is here set up.

It is worthy of note that the judge in this case apparently thought that it was the duty of the architect to see that his client had a fair understanding that the architect expected to be paid or that the facts must be such as to compel him so to understand.

As to the fourth proposition that I have laid down, namely, "That no claim can be based on services offered by way of tender, nor does any obligation arise on a call for services of a like nature," little more need be said than to illustrate my meaning. If an architect offers, even though at the request of the owner, to prepare drawings on the chance of obtaining the work of superintending the proposed building he can maintain no action for payment unless his plans are used. This is quite apart from the question of approval. In fact, although quite satisfied with the drawings the owner may abandon the idea of building without incurring liability, and a public advertisement for drawings of such a nature imposes no obligation to accept any.

How fine the dividing line sometimes is between an order for work and a mere tender may be seen from a case in Lower Canada in which the architect succeeded. Drawings were invited for a church, not to exceed a fixed sum, on the condition that the unsuccessful competitors should receive a certain premium, but the architect whose plans were selected was to receive no premium, but to obtain the work of superintending the building. The plaintiff's plans were approved, but it subsequently appeared that they did not comply with the conditions and were rejected. This would appear to some as near as possible to a case of tender in the hope of being retained if the plans were approved, but the court held that the architect was entitled to recover and allowed him one per cent. of the limited cost of the proposed building.

I fear I have dwelt on this subject of contract or no contract so long as to be tedious. I shall dismiss it with this one remark: although the general proposition that a man is entitled to be paid for his services is admitted, there seems to be an inclination to regard architects' drawings as always tentative offers in the absence of definite evidence to the contrary, thus throwing the onus on him of establishing a contract, as shown by the American case which I have cited.

It is a relief to leave the shifting sands in which we have been endeavouring to pick our steps. Where the parties themselves were not quite sure of their intentions, and have left so much to inference, a lawyer's conclusion on a case submitted to him is likely to be preceded by a series of "ifs"—if your contract means so-and-so, then this is the law; if your agreement were otherwise, then the law is otherwise; and if a law suit follows, and there is, (as is sure to be the case), a conflict of evidence, the verdict satisfies no one, and judge, jury, and lawyers all fall into the same condemnation. Be advised, therefore, and do not fail, either from feelings of delicacy or from confidence in your own powers to give satisfaction or in your employers honour, to have the terms of your agreement reduced to writing; and if the nature of the case is such as to render a formal agreement unnecessary or ill-judged, at any rate write your client a letter, setting forth your understanding of the arrangement, and if he acquiesces, you have a written agreement; and if he does not expressly do so, his silence will be strong evidence of his approval.

There is another point in the making of these contracts in regard to which architects would do well to be wary, I mean in assuming the duty of drawing the contracts between owner and contractors. There is no authority on the subject, but it may safely be assumed that it is no part of the architect's duty, and I am confident that no such custom should be proved. If, therefore, the architect undertakes to draw the contract, whether by or without the request of his client, he assumes work for which he is not paid, unless by special agreement that he should be paid extra. While, however, it is true that in so doing without payment he assumes no great responsibility, being liable probably only for gross negligence, yet if he be paid for it he will be bound to exercise reasonable skill and will be held to a strict account, and that too for work which is not within his province. And it must not be forgotten that the contention that he has not been paid for drawing the contracts would probably be met by the conclusive answer that having undertaken the work, payment is included in the fees.

If, however, at the request of your client, who may be unwilling to incur the expense of employing a solicitor, you agree to draw the contracts, allow me to offer a practical suggestion—see that the contractor reads and understands his contract, otherwise you may find yourself in the unenviable position of being obliged to act as the task master of an unscrupulous man who has no compunction in holding an unfortunate contractor to harsh conditions which he has probably signed without reading. A good instance of this sort of thing is to be found in the case of Jones v. St. John's College, Oxford. In that case the builders undertook to erect and complete a building by a certain fixed day and to execute such alterations as the clerk of the works might order within the time limited for the completion of the contract unless an extension of time were allowed, and in default to pay a fixed sum per day. The builders neglected to obtain an extension. The clerk of the works ordered alterations which it was impossible to complete within the time agreed, in fact the work was not finished until some time after. The owners insisted on the exactions of their penalties, and the unhappy builder was mulcted in a large sum.

I come now to a question which has always been a sore point with architects. Where plans have been prepared, and the architect's fees paid, but the architect is not retained to superintend the building; in the absence of agreement, to whom do the plans belong? This precise point has never been expressly decided. The architect says they are his, and relies upon an alleged custom among architects, that in the absence of other agreement the plans remain the property of the architect. Where the building goes on and is completed under the same architect, little if any difficulty is likely to occur in practice, as the architect gets his full remuneration. The trouble arises when the client by claiming the plans without building, is in effect getting the benefit of the architect's work and knowledge for a much smaller fee than the latter would demand if he had anticipated the result. However, it seems from a case decided in England some years ago, as if the architect's view is not likely to be taken when the question comes up for decision. In the case I refer to, the owner after the completion of the plans determined not to go on with the building, and asked the architect to send in his account and the plans. He refused, however, to give up the plans, setting up an alleged custom among architects, that in the event of an employment of the architect being stopped, he was entitled to be paid for the plans and to retain them. The learned judges in discussing whether such a usage would be reasonable, even supposing it was properly proved, used some pretty stroog language; one of them said that: "It appeared contrary to reason, good sense and justice, that in the event of a contract being put an end to, the architect should retain the plan for which he was entitled to be paid; it would require at least a clearly expressed stipulation in the contract to enable him to do so. The defendant was perfectly justified in refusing to pay until he had the plans. The execution of and the plans themselves formed the work and labor for which he charged the defendant, who was entitled to them if he had to pay for them."

Another judge was even stronger. In his opinion the usage contended for was impossible; he could not help saying that it was perfectly suicidal; so soon as it was brought into being it cut its throat with its own absurdity. "In all common sense," he exclaims, "a man is entitled to what he is compelled to pay for." Before usage could be insisted on, it must be proved to be one well known to prevail. It required the most rigid proof that it actually existed.

I have cited this case somewhat at length, by way of illustrating what I have already said as to the difficulty of proving an alleged custom, and also to show the strong leaning of the Court against this custom in particular; and although, as you will notice, this case does not actually decide the point as to the ownership of the plans, it must be admitted that it trenches very strongly on the architect's position. What it does actually decide is that when an architect agrees to prepare plans and to superintend the erection of a building for which he is to receive a certain percentage in respect of the plans and a certain percentage for the superintendence, if the owner, not having bound himself to build, abandons his intention after the preparation of the plans, the architect cannot recover his charges for the plans without delivering them to his client. Whether the latter can subsequently use them, and in so so doing employ another architect, was not decided. To do so would probably have been a violation of his agreement to employ the plaintiff, for which he would be liable in damages. As far as we can judge from the report, he had entirely abandoned the idea of building. But I do not think that the judges meant so to restrict the effect of their judgment. If so, why the indignation at the architect's contention? If they thought that all the defendant was entitled to was the barren possession of the plans, the emphatic language with which they denounce the architect's refusal to grant so useless a privilege was out of place. They seem to have been clearly of the opinion that the defendant had bought the plans out and out. Perhaps if the architect had been able to put aside the agreement and sue for a quantum meruit, as it is called, that is to say, for a reasonable amount for the time and trouble spent in the preparation of the plans, the result might have been different. However this may be, the broad proposition asserted by architects, that in no case do the plans become the property of the client, seems untenable. It has the appearance of an artificial endeavor to get over a difficulty to which they are liable from the very nature of the case. No doubt it is a hardship that your work should be used by others than those who pay for it, or for other purposes than you originally intended, but it is a hardship to which other professions are also liable. If I employ a celebrated painter to execute an order for me, it would be absurd to contend that the only right I possess in the picture is the right of enjoyment. The truth is that the painter is surrounded by the natural protection arising from the fact that the painting is his production and his only, and no copy can be the same thing. But a copy of an architect's plans are quite as effectual as the original, and being deprived of this natural defence, he is driven to assert a claim which in the other case is admitted to be absurd. Nor is the illustration weakened by the fact that the Legislature has seen fit to afford further protection to pictures and other such works of art, by copyright. This merely serves to show that the hardship which is admitted to exist can only be remedied by legislation, and not by the assertion of a custom, which is apt to ignore the fact that

in protecting its exponents, it in some cases works a correlative injustice to the other party by giving him absolutely nothing for a very fair fee. However, there is no reason why this should ever be more than a theoretical difficulty, if architects were to take the precaution of inserting in their contracts a provision that in any event, the property in the plans remains theirs.

Before leaving the subject of the plans, I may mention that it has been decided that the employer does not guarantee to the contractor the feasibility of the architect's drawings, and in a case where the contract provided that certain caissons to be used in the building of piers, were to be made of the materials and in the form shown by the drawing, it was found that the proposed method was unworkable, and another plan had to be adopted, and although the contractor was put to a good deal of extra expense, he failed in an action against the employer to recover the amount. He would have been equally unsuccessful in an action against the architect, because of the want of privacy between them, and the suit would have been dismissed without coming to a hearing. The rule is that no action for a wrong can be maintained, unless the wrong complained of arise out of a contract or from the violation of a duty.

The extreme limit of this doctrine will appear from a case which has the appearance of working great hardship, if not of doing a real injustice. A person who proposed advancing money on a loan by way of mortgage on a building, wrote to the firm of valuators employed by the owner, telling them of his intention and asking their opinion on the value of the buildings, and the advisability of the loan. The valuators, by gross carelessness, gave too large a value, and the mortgagee suffered a loss in consequence It was held that he could not recover against the appraiser. It will be noticed that there was no contract between them; the defendants had merely given a gratuitous opinion, on which the mortgagee might act or not, as he pleased, and that there was no duty imposed by law on the defendants to show any degree of care towards the plaintiff, as long as they avoided actual fraud. Applying this rule to the architect's specifications, it follows that a builder cannot obtain redress, should he suffer loss by relying upon them; he must satisfy himself before tendering of their feasability.

I have left as the last question for discussion, what is perhaps the most interesting of all, namely, the owner's right of action against the architect for negligence. Until lately the views of the public and of the profession have diverged on this question, quite as emphatically as on the right to the plans, but recent decisions in the United States have happily set the architect's position on a better footing.

The lay view may be stated somewhat as follows: An architect is retained to see that the builder carries out his work properly, and if the builder scamps his work or makes a mistake, the architect must pay for it, because this is what he is retained for; in other words, that the architect guarantees the competence and good faith of the builder and his men.

The architect on the other hand submits that even if perfect accuracy were possible, to insure this he would have to be in constant attendance at the building, and even in two or more parts of it at the same time, and that the remuneration he receives would be no compensation even for the less difficult of these tasks.

The layman's view, it will be noticed, assumes that any imperfection is conclusive evidence of negligence, while the architect says, "I admit my liability for negligence, but it must be brought home to me on the facts of each particular case."

The difference between these two views is fundamental, as will presently appear. In the English cases we have very little to help us on this point, perhaps because the architects there are better advised than to bring the actions which are common enough in the States and in this Province, or perhaps because English architects are more careful. The general proposition which the law lays down is this: Every professional man guarantees that he possesses a reasonable degree of skill in his profession, and that any work entrusted to him will be carried out with reasonable care, and he is liable in damages if he fails to display such skill and care, and loss ensues to his client. The utmost skill attainable is not required of him, but only a reasonable amount, and this will differ according to circumstances. If I employ a village architect whose highest flight has, to my knowledge, been the village inn, to build a concert hall, I cannot complain if the acoustic arrangements are defective.

But in the matter we are now discussing, the question of liability generally depends, not so much on the degree of skill displayed, as on the care shown, or, rather, absence of care, that is to say, negligence.

In one of the American cases to which I have referred, the contract with the mason provided that he should lay out his work himself. When the wood was nearly completed the sills of the front first-storey windows were found to be set 2¾ inches higher from the floor than those of the rear windows on the same storey, although they were intended to be on the same level. When the finish was put in, the trim of the windows cut into the plaster cornice, injuring the appearance of the room. In a suit by the architect to recover his charges it was referred to a referee, who found on the evidence that the plaintiff had bestowed as much personal attendance upon the building as was necessary, and that the variations mentioned were not caused by carelessness, negligence or inattention on his part. This decision was reversed by the Superior Court, but restored by the Court of Appeals. The Court said, It, (the defect), arose from the masons not having accurately conformed to the specification and plans. Was the plaintiff responsible for the fault of the masons? The plaintiff agreed to make plans, sections, elevations, and specifications, and to superintend the progress of the building to be erected. It was not his duty to do the work. I do not think it was the duty of the plaintiff to measure the joists or timber of which the different storeys were to be constructed, and to determine by actual measurement that the ceiling of the first story had an elevation of 13 feet, and the second had an elevation of 11 feet, or to measure the thickness or depth of the brick or stone walls. The defendant however contends that the obligation of the plaintiff to superintend the progress of the building bound him to discover and correct the error committed by the mechanics. The plaintiff did assume the superintendence of the erection of the building, and must meet the obligations of his contract. The plaintiff came from day to day to superintend the progress of the work, and while thus superintending was he bound to have ascertained that the window sills in the front parlor were 2¾ inches higher from the floor than was authorized by the plan? He, (the referee) found that the plaintiff had bestowed as much personal attention on the building as was necessary, and that the variations mentioned were not caused by carelessness, negligence, or inattention on his part. I do not find it necessary to differ with him."

I take the liberty of quoting from the judgment in another New York case, in which the question is discussed if possible with even greater clearness than the last.

"The learned counsel would not claim," says the judgment, "that an architect is bound to spend all his time at a building that is going up under his professional care, so that no fraud or negligence can be committed by any of the contractors. The counsel would not contend that the architect is an insurer of the perfection of the mason work, the carpenter work, the plumbing, etc. He is bound only to exercise reasonable care, and to use reasonable powers of observation and detection in the supervision of the structure. When therefore it appears that the architect has made frequent visits to the building, and in a general way has performed the duties called for by the custom of the profession; the mere fact, for instance, that inferior bricks have been used in places, does not establish as matter of law that he has not entirely performed his contract. He might have directed at one of his visits that portion of the plumbing work he packed in wool. Upon his next return to the building, it might have been covered with brickwork in the progress of the building, If he had enquired whether the wool packing had been attended to and had received an affirmative answer from the plumber and the bricklayer, I am of opinion that his duty as an architect in the matter of the required protection of the said pipes from the weather, would have been ended. Yet under these very circumstances, the packing might have been intentionally or carelessly omitted, in fraud upon the architect and owner, and could it still be claimed that the architect had not fully performed his work? The learned counsel for the appelant is in effect asking us to hold that the defects of the character above named, establish as a matter of law, that the plaintiffs have not fully performed their agreement. An architect is no more a mere overseer or foreman or watchman than he is a guarantee of a flawless building; and the only question that can arise in a case where general performance of duty is shewn, is whether, considering all the circumstances and peculiar facts involved, he has or has not been guilty of negligence. This is a question of fact, and not of law.

It is perhaps necessary to add that in this case the architect had not given his final certificate, and left the building with this manifest defect in it. He had, in fact, refused to give the contractor a certificate, and the owner had settled with the latter in spite of this. But the judges refused to base their decision on this ground. They treated it as a question of negligence or no negligence on the part of the architect, but you will notice that from the peculiar facts of the case, the point for their decision was this, Did the failure of the architect to detect the error at the time it was made establish negligence? The referee had found no negligence, and the Court refused to differ with him, thus treating the alleged negligence as a question of fact and not as an inference of law.

Let us consider now how the architect's liability for negligence has been dealt with in this province.

I find a case referred to in the October number of the CANADIAN ARCHITECT AND BUILDER. The plaintiff, who was obliged to sue for his fees, had been employed to superintend the erection of an hotel in a country village. The defendant set up that there was a defect in the building for which the architect was responsible. The defect complained of was a slight sinking of the floor in the centre of the building, and showing in one of the principal rooms and the main hall. The amount that the floor was out of level was one-thirteenth of an inch to the foot one way, and about one-sixth of an inch across. No plaster was cracked, no doors bound, and no inconvenience of any sort was occasioned. From the report of the case, it does not appear that evidence was adduced to show that the architect had been sedulous in his attendance at the building, nor does any evidence appear to have been offered to prove the contrary, but it was shown that the architect had himself levelled the ground floor joists when they were laid, and left them true and level. The judge, in summing up the evidence, said that undoubtedly there was a defect in the building, and he gave judgment for the plaintiff with costs, less a sum which it had been shown it would require to raise the floor and make it level.

Here we have a case in which the judge was evidently imbued with the idea that wherever a defect occurs, the architect must pay for it. That is to say, in direct violation of the principle laid down in the cases which I have cited, he regarded the mere existence of a defect as conclusive proof of the architect's negligence. Assuming the case has been accurately reported, one would think in the absence of evidence showing that the failure of the architect to discover the error was due to his want of skill or neglect of duty, and no such evidence appears to have been offered; that he had faithfully discharged his duty in levelling the joists himself, and seeing that they were true and level. If architects are to be held to so strict an account as this, their only safety will lie in employing a clerk to be in constant attendance at the works, and putting the charges up accordingly.

If in an action by a surgeon to recover his fees, he were met with the defence that the operation which he had performed had left an unsightly scar, it would be rather a startling conclusion, if the judge without any evidence of negligent or improper treatment, were to lay down the proposition, that as the scar undoubtedly existed, the surgeon must reduce his charges as compensation to the defendant.

But on the other hand, it must not be forgotten that a judgment in a decided case is only of authority for the precise point there decided, and that while the principle laid down by the American cases to which I have referred, seems to be sound and to establish all that architects need reasonably ask, it would be very dangerous to act on the illustration given in one of them, as a rule of practice. I refer to the judge's opinion in the case put by him of the pipes which required to be packed in wool. There are times no doubt in the erection of a building, where the architect's attendance is required to be more frequent than at others, especially where work is being done which can be speedily covered, and it may well be that a jury would be justified in finding negligence, in spite of the most careful enquiries on the part of the architect to ascertain the truth, if at such times work were improperly done during his absence and covered; and again the defect might be so great and the neglect so gross as to justify an immediate finding of negligence which could not be upset by any amount of evidence of careful attention to his duties on the part of the architect. But if the principle laid down in the State of New York finds acceptance in Ontario, architects have the satisfaction of knowing that their liability for negligence will in future depend on the facts of each particular case as established by the evidence, and not on any preconceived idea of his duties in the minds either of judges or juries.

At the conclusion of the paper the President expressed the pleasure and satisfaction he had had in listening to it, and tendered the thanks of the Association to Mr. Gwynne.

Mr. Dick, in seconding the vote of thanks, said that Mr. Gwynne's paper was a very valuable contribution to the literature of the Convention, and when published in the CANADIAN ARCHITECT AND BUILDER would enable architects to avoid many of the pit-falls and snares to which they were exposed. While listening to it he had been impressed with the idea that the life of the architect, like that of Gilbert & Sullivan's policeman, "was not a happy one," because he was always exposed to two fires, the client on the one hand and the contractor on the other. There seemed to be a good deal of uncertainty in the law, and in many cases the decisions seemed to hinge a great deal on who was the judge. There was a certain amount of consolation for the architect in the paper, however, in regard to his liability for defects in workmanship, or for careless, slovenly or scamped work. In regard to the question of the ownership of plans, it seemed to him that where a proprietor paid a recognized fee of two-and-a-half per cent. he was fairly entitled to the plans. He thought it was fair and right that architects should retain copies of plans for their own future reference, but where a client paid the two-and-a-half per cent. which was recognized as the value of preparing plans, he thought it was not unreasonable that they should become his property, especially where he abandoned the idea of building. Of course if the architect believed he was going to be employed to superintend the work at the full commission, and then the owner, under the impression that he could get the superintending done cheaper, should say, "I will pay you for the plans," it would be a rather shabby thing on the part of the employer, though he did not know that morally the architect had very much ground for complaint as long as he got his fair proportion. These commissions, while purely arbitrary, were after all a very fair way of arriving at the value of certain services.

Mr. Langton said he was glad to think that the general drift of Mr. Gwynne's advice to architects was hopeful; that the trouble which was sometimes encountered in settling with clients, and at times, when driven to the last resort, in obtaining a verdict from a jury, could be obviated by taking a little pains in the first instance to give a clear understanding of what the architect expected to receive. In regard to the ownership of plans, it had always seemed to him that the owner had a right to plans, but there ought to be some means of preventing him from regarding the plans as his property to be used again, as for instance, where a design has been supplied for one house and the proprietor subsequently puts up a row. He thought some rights ought to be reserved to the architect in his plans, although no doubt the owner had a right to receive that for which he had paid.

Mr. Burke said that architects when settling up with clients were frequently met by a request that now the building is finished he will hand over the plans. He thought experience dictated the handing over of the plans, because an architect might leave the country, and in a year or two if the plans were wanted they could not be obtained.

Mr. Baker thought the plans without the specifications did not amount to much, as they would not be very intelligible to a builder without the details.

Mr. Dick related an instance where there was a stoppage of the drains in a house, and when the owner who possessed plans was asked where they were she did not know. He thought that was the usual state of affairs. He had understood Mr. Gwynne to say that a proprietor did not guarantee the infallibility of the plans to the contractor, and he would like to know how far that principle applied, because in some instances it might work rather a hardship on the contractor. Suppose a foundation wall was designed too thin to carry the wall above it, would that be a case in which the owner of the building might call upon the contractor?

Mr. Gordon said the question of responsibility was a very broad one, and there was one aspect of it which might be mentioned. There might be points in connection with the drainage or other details which might be covered up, and on which the architect might certify, and the whole transaction be closed as far as the proprietor and contractor were concerned. A year or two after something might transpire which would disclose to the owner for the first time, and also to the architect, that there had been crooked or negligent work on the contractor's part, and the point might be raised that it was the duty of the architect to have investigated. As they all knew, the responsibility of an architect was by no means ended when he was paid his account. The case he had supposed was not at all a fanciful one; he thought there was no architect in the room who was not cognizant of such cases. He did not know of any instance in which an architect had actually been sued, but they had been threatened, and it certainly appeared as if they were open to proceedings. It had always appeared to him that there must be some way of wording the final settlement between proprietor and contractor which would, at least to some extent, protect the architect against these unforseen contingencies, and he thought it was time very close attention was given to the form of both progress and final certificates in order to attain that end.

Mr. Wickson said that in some forms of contract it was specially stated that the final certificate did not exonerate the contractor from liability.

Mr. Gordon suggested that in the meantime the contractor might have failed in business.

The President then put the motion for a vote of thanks, which was carried very heartily.

Mr. Gwynne, in acknowledging the vote of thanks, said that with regard to the last point raised, it must be borne in mind that no general proposition of law could be laid down, each case always depending on its own state of facts, but if as in the supposed case a defect subsequently appeared, it became simply a question of whether such defect was due to the architect's negligence; and the greater the length of the period between the erection of the building and the discovery of the latent defect the greater the difficulty in showing that it was due to negligence, and the more difficult would it be to succeed against the architect.

Mr. Helliwell said that before the subject was dropped there was another point he would like to raise, that was the difference between the duties of an architect and a clerk of the works. In the erection of larger buildings it was usual to employ a clerk of the works who spent his entire time on the building. The supervision of such a man must manifestly extend further into the minor details than that of the architect. He thought if the distinction between the duties of an architect and those of the clerk of the works was more sharply brought out it would prove beneficial to all concerned. It ought to be clearly understood that the architect was only responsible for the general supervision of the work.

Mr. Townsend said he had adopted a course which he thought quite covered the whole question of the ownership of the plans, remuneration and many other points, that was to send his clients a copy of the little pamphlet containing a schedule of fees and other conditions of service and ask them to read it over, as being the terms under which he would act.

The President said he had done the same thing, and in one instance a client had signed the pamphlet.

Mr. Pearson said he would like to refer to the clause in the contract providing for the payment of a penalty by the contractor for the non-completion of work by a specified time. He believed that it was held that to succeed under that the owner had to show actual damage sustained by reason of not having the building at

the stated time. In conversation with the solicitor for one of the railways, that gentleman had suggested as a better way of arranging it that the builder should receive a certain sum if the building was erected at a certain date, if not completed by a certain later date also specified, a smaller sum, thus reducing the amount to be received by him as the time was prolonged. He would like to hear a little discussion on that point.

Mr. Wickson wished to know to what extent an architect was supposed to keep track of this matter. If a client goes to the architect and inquires whose fault it is that the work is behind, the architect may say it is none of his business to know. To whom can the client look? It was his own practice to keep a diary, making note of the progress of the various works almost every day, and he had given a client who made such inquiries a copy of that as nearly as he could. The client afterwards told him it was the most non-committal letter he ever got, but he did not know that he had a right to give him even that information. It was always a very awkward matter to say just who was behind.

The President said he thought the best way was to leave the drawing up of the contracts in the hands of lawyers, because the architect had quite enough responsibility without that.

Mr. Baker had found the bonus system to work well, generally resulting in getting the work through in good time.

Mr. Burke said the difficulty was where there were different contractors for the various trades to locate the blame for delays; he had found it almost impossible to do it.

Mr. Langton said an architect very often found himself bound to carry out what was really an injustice. Where a man had a time contract to carry through, and he was thrown out of his arrangements by delay on the part of those who had preceded him he could no longer do it for the same money, and might very justly say, "I cannot afford to do this work as quickly now as I could before."

Mr. Wickson said he had mentioned that very point to a client, and the client's reply was, "The man should not have been such a fool as to sign the contract."

Mr. Wickson's resolution regarding the printing and distribution of the President's address was then carried, after which the meeting adjourned until Wednesday morning.

SECOND DAY.

The proceedings of the Convention were resumed at 11 o'clock, by Mr. W. A. Langton reading some "Notes of an Architectural Tour in England and France."

Mr. Langton's paper which was illustrated in a very interesting and instructive manner by stereopticon views of the examples referred to, was received with much interest, and called forth very hearty expressions of approval.

Mr. Townsend opened the discussion by saying that he thought the lesson inculcated by Mr. Langton's address was, that there should be on the part of the architect less striving after originality in order to show what he could do, more common sense building and less architecture. He thought that applied more to residence designs than anything else. The speaker had told them what probably many of them had noticed, that in London and Paris the best work was that which was simply the outcome of an intelligent appreciation of and supplying of what was needed in each case. For instance, the building by Mr. Norman Shaw which had been illustrated was simply a square building which, while preserving good proportions throughout, placed the rooms and windows where the proprietor wanted them. Other buildings in which a great effort at display was attempted they had been told were not successful, and he thought that would always be found the case.

Mr. A. E. Paull expressed his gratification at the manner in which Mr. Langton had handled his subject, and suggested that if on a future holiday trip Mr. Langton could visit Vienna, where he thought greater strides had been made than in either London or Paris during the last generation, and at a future meeting of the Association give them the results of his observations there in a similar form, it would be highly instructive and beneficial. It was said that Vienna had more valuable architecture than any other capital in Europe. He had very great pleasure in proposing a vote of thanks to Mr. Langton for his very valuable contribution.

Mr. Townsend, in seconding Mr. Paull's motion, remarked that the members of the Association ought to endeavour to impress the lesson of Mr. Langton's paper upon their clients in residence work; he thought if they could be induced to take into consideration the value of the court it would have a very beneficial effect.

The President, in closing the discussion, said one of the principal lessons to be learned was the cultivation of a feeling of restraint among designers, and a sense that every other man had some rights which ought to be respected. It would be impossible to have a street satisfactory from an architectural point of view if every man insisted upon building as if his was the only house upon that street. New York was said to possess some fearful examples of the disregard of this principle; charming residences were found standing between two monstrosities. Abroad the cornice lines and the main lines were run as far as possible in accord with those on either side of them. He was aware that the problem was surrounded by very great difficulties, but at least an effort should be made in the desired direction. Mr. Langton had said that what most impressed him in Paris was the prevailing color. Owing to that feature the individual house was lost sight of, it was the whole street that gave the impression. Here it was unfortunately the case that even where two buildings side by side were being erected at the same time men would not take the trouble to inspect each other's work, or find out what the other man was going to do. He advocated the casting away of all little, petty jealousies, and a united effort to promote a more uniform style of building.

The vote of thanks to Mr. Langton was then carried unanimously.

A paper was then read by Mr. Andrew Bell, of Almonte, on "Building Stones of Eastern Ontario."

Mr. Bell's paper was followed by an adjournment to an adjoining room, where samples of the various kinds of stone were inspected, and conversation indulged in by the members regarding them in relation to Mr. Bell's address.

Mr. W. R. Gregg, seconded by Mr. Belcher, moved a vote of thanks to Mr. Bell, which was carried.

The Convention then adjourned for luncheon, which was served in the building.

AFTERNOON SESSION.

In the afternoon the first number of the Agenda was a paper by Professor Ellis, on "The Chemistry of Paints."

Professor Ellis's contribution was not committed to writing, but he spoke as follows:

"Being practical men, the members of this Association will expect me to treat of the practical rather than the aesthetic side of this subject, which, however, is one that lends itself readily to treatment from either point of view, because paints are decorative and protective. It is from the protective point of view I am going to speak. Of course, when you change your point of view, the whole subject in this respect is entirely changed, because from the decorative point of view the pigment is everything, while from the protective standpoint the oil is everything, and the pigment is of no importance except in so far as it hastens or retards the process of drying.

It will of course be understood that my remarks must of necessity be of a general character. The use of paints as a protective arises in this way. The cause of decay we will speak of (because we know it is to timber that paint is most commonly applied) is the growth of mushrooms in the timber. Now, we know that when a man wants to grow mushrooms he first

obtains a mushroom spore, and then selects a warm, damp spot in a cellar, out of the light, and provides a bed of decaying organic material and there sows his mushroom spore. He maintains a moderately warm temperature, and then the mushrooms will grow and multiply. Now we know that decaying wood is nothing but a decaying mushroom bed, we know it decays because the mushroom spores get into various lodging places in it, and there develop, and in the act of so growing disintegrate and destroy the wood. Therefore, in order to preserve wood from decay, all we have to do is to prevent the mushrooms from growing in it. Of course I do not mean edible mushrooms, but plants, whether large or small, of the same botanical nature as the mushroom which grow and are propagated in the same way, by means of minute spores.

If you take an ordinary mushroom and lay it on a piece of paper when it is ripe, an impalpable powder will drop from it on to the paper. These are the mushroom spores. These, when submitted to suitable conditions, warmth, moisture and, preferably, darkness, will grow. In fact the requisite conditions are very much the same as required to germinate grain. Therefore the first thing to be done in order to preserve timber is to exclude these spores, and if you succeed in doing so it will not rot or decay. I will assume that the spores are not in the wood when it is cut. That being the case, if it can be completely covered in such a manner as to prevent these minute particles or spores from gaining access to it, then it will be preserved indefinitely from rot. If the spores are in the wood when cut they can be destroyed by exposure to a sufficiently high temperature, and then the entrance of other spores can be prevented in the way I have already stated. The spores may also be killed by applying anything that will poison them, and various antiseptic solutions have that effect. The spores have a very considerable resistance to deleterious agents; they may be frozen, dried up, and so on, and and still will come to life again, but they can be destroyed by heat and by many antiseptic solutions, such as corrosive sublimate, creosote, etc.

In order to protect wood, if it can be covered over with a substance which does not afford nourishment for these spores, and which they cannot penetrate, it may be preserved. Now oils and fats have long been regarded as preservative, in this way. It is found that oils vary very much with regard to their behaviour when spread in a film over any surface. Some oils are practically unchanged, others become changed into a hard, somewhat elastic, insoluble substance something like India rubber or leather. These oils are known as drying oils, and of these drying oils the one which shows those characteristics in the most marked degree is linseed oil, while olive oil may be taken as an example of the other class. Here is some olive oil and some linseed oil which have been spread on pieces of glass and exposed to the air at a temperature not far removed from that of boiling water. That temperature was adopted simply to accelerate the drying process, the result is better obtained by exposing them to the ordinary temperature. You will notice in these specimens that the olive oil is unchanged, it is just exactly as it was when placed on the glass, while the linseed oil has become a hard and firm film or coating on the glass. That is the way in which drying oils behave, and it is that which gives them their value as protectives. Oils when fresh are very soluble in ether, for example, but after drying, the drying oils become insoluble in ether, while the non-drying oils have their solubility unchanged, so that the nature of the oil is profoundly affected by the the drying process. The film is elastic, and resists moisture, and therefore anything which is coated over with this film cannot be effected by moisture.

Now I pointed out that drying up would not destroy the mushroom spores, but so long as they are kept dry they will not grow, so even if they are present in the wood they will not grow so long as they are kept dried up. This film therefore serves a double purpose; it forms a waterproof coating for the wood, and prevents the entry of the spores from without. Of course if the wood is moist when the paint is put on, it will keep it moist, but if the wood is dry it will keep it dry.

Now, what I propose to discuss is, what is it that causes this difference in the behaviour of drying and non-drying oils, so far as they are known to science, which is only in part. The first point is that the change is due to oxidation; the drying oils oxidize when exposed to the air, while the non drying oils do not. This can be shown in various ways. For instance, if they are kept at an ordinary tempetature for some days in thin films like this, these drying oils increase in weight, and the others do not. You know that certain oils when exposed on a large surface to the air will combine with the oxygen of the air so vigorously that they catch fire. For this reason it is well known that greasy cotton waste frequently becomes a dangerous element. The reason for that is that the cotton waste is saturated with it and a very large surface exposed to the air, and the oxidization produces heat which ultimately sets fire to the oil. Drying oils are very much more likely to ignite under these conditions than non-drying oils. Experimentalists have found that by taking cotton waste and soaking with non-drying oil, and heating it to a little below boiling water it may be made to take fire in an hour, while drying oil would not take fire under those circumstances until after being very much longer exposed to the heat. It has also been found that this oxidation of oils can be hastened by blowing air through them, and it is by raising the temperature. For instance, if oil is heated to 130° C and a current of air passed through it, it undergoes changes which make it dry much more quickly. In what is called "boiling" oil, oil is heated to 130° C and over, and a certain portion of the oil is decomposed, and the resulting product will dry very much more quickly than raw oil. Then, again, it is known that certain substances when they are mixed with oil, either during the boiling or afterwards, have the property of hastening the drying very much. These substances are called dryers. Some of these substances are black oxide of manganese, red lead, litharge, oxide of lead, these assist very much in drying the oil. Oxide of manganese is well known to be a substance which gives off oxygen very readily, and red lead also gives up oxygen."

Professor Ellis then, using the blackboard, gave a number of chemical formulæ illustrating the action of the various drying substances in connection with oil.

Proceeding, he said, "Now it is a well known fact drying in paints depends not only on the oils, but the different colors exercise considerable effect upon the oil. Of course it is easy to see how red or white led would hasten the drying process, because we have seen how that it is effected with the oil. White lead is known to dry well, and it probably undergoes some similar change, and it probably forms the same kind of oxide that red lead does. I asked Mr. Elliott the other day to give me a list of the colors that dried well. The quick drying ones are yellow ochre, chrome green, zinc white, white lead and sienna. The slow drying colors are lamp black, madder, prussian blue, lakes, carmine, and with these latter Mr. Elliott told me it was necessary to add dryers in order to make them dry. The colors which dry well are almost all mineral oxides, while those that dry slowly are organic compounds. They have a tendency in chemical reaction to take away the oxygen, and therefore it appears that these colors hinder the oxidization in that way, while mineral colors assist them."

The President inquired if color were no object, would oil alone be better?

Prof. Ellis replied that it would not.

The President further inquired whether if a mixture is to be made, red lead was the best thing to use with the oil.

Professor Ellis said that probably some substance mixed with the oil would make a better covering than the oil alone, but he was not prepared to say that red lead was the best substance, because it was desirable that the substance used when once dry should be as unchangeable as possible, and lead was certainly not such a substance. Oxides of iron, such as ochre, were

very unchangeable, a priori he would say they would be very good materials to mix with oil.

Mr. A. F. Paull inquired if Prof. Ellis could recommend anything for the prevention of dry rot better than corrosive sublimate.

Prof. Ellis answered that so far as he knew corrosive sublimate was the best thing to use to destroy the spores. Of course paint did not destroy the spores, but merely assisted in keeping them out, and as soon as it cracked they could enter through the cracks.

Mr. Gregg, following up the question put by the President, asked whether the same objection that had been spoken of as to red led existed when the red lead was used for priming for which it had always been understood to be a good substance and two or three coats of another color applied afterwards.

Prof. Ellis answered that he thought it did not; he had only mentioned the objection to red lead because it was more liable to change, and was not so permanent as other colors.

Mr. Dick said that in the earlier part of his lecture Prof. Ellis had made some very practical remarks in regard to the properties of timber. An illustration in connection with this occurred to his mind, and no doubt others present had met with the same thing in the course of their work in the case of a warehouse, for example, where a row of columns was run through the length of the building and a beam resting from column to column, just resting upon each column. The difficulty to be contended with was, that this beam was a little unsightly if left in its natural condition; while, on the other hand, if painted, it was well known what consequences might be expected. Generally speaking in a not very long time rot would be found somewhere in that beam. He presumed from the warmness of the building and the natural moisture not being dried out of the timber, this mushroom growth spoken of by Dr. Ellis set in. He supposed the spores must have been present in the wood in the first place. He had often himself, and he supposed others had done the same thing, left beams just as they were, unpainted, for a year or two, until they were thoroughly dry, and then had them painted. It had occurred to him that it might be a good thing to leave such a beam unpainted for a year or two, enveloping it in the meantime in cotton batting, until it has become thoroughly well seasoned. The effect of the cotton wool, he thought, would be to filter the air that reached the beam and retain a great many of the spores in the cotton. It would be worth trying as an experiment he thought. Whether the rot was caused by the mushrooms spoken of by Dr. Ellis, or some other organisms, he did not know, but the fact was undoubtedly that in every case where beams were painted the rot sooner or later made its appearance.

Mr. A. F. Paull asked Mr. Dick if he thought that such a beam as would be required to sustain a number of joists in the way suggested, if left in its natural state for two or three years, would then be sufficiently seasoned to admit of its being painted with safety? Professor Barlow, whose works were published, and who had made experiments with regard to the seasoning of timber extending over fifteen or sixteen years, had discovered that at the end of that period the seasoning process was still going on. If Prof. Barlow was right the prevailing opinion was that wood became sufficiently seasoned after two or three years to make it prudent to apply paint was wrong.

Mr. Dick thought practical experience had demonstrated that in most cases two or three years was a sufficiently long period for the beam to get seasoned in, but Mr. Paull was quite right in saying that wood scarcely ever ceased from the process of seasoning. He knew of a case where an old deal table which had been in use for some twenty years in a building insufficiently warmed by the ordinary stoves had been moved into a new building heated by steam, and it had not been there very long before one day it went off like a pistol shot, cracking its entire length.

The President related an instance which occurred in England, in which some old beams taken out of a church were sawn up for another purpose, and they afterwards both warped and cracked, and if anything might be expected to be thoroughly seasoned certainly those beams might have been.

Mr. Belcher remembered a case where an old hardwood floor was taken up, the boards re-dressed, the joints shot, and the floor re-laid, the joints being cramped up perfectly tight, the boards dowelled together and everything left perfectly tight. About two months after it was found that one might almost put a penny piece between the joints of the boards in places. He attributed this to the fact that the old flooring had been left out of doors for a short time during the process of the work, which occupied about two weeks, and had absorbed moisture. The floor he had no doubt was at least two hundred years old.

Mr. Townsend said one of the great difficulties architects had to contend with was that of not being able to get what they specified, particularly in the matter of oil. He understood from what Dr. Ellis had said that the value of paints depended almost entirely on the quality of the oil used, and if Dr. Ellis could give some rapidly applied test, by which, without any deep knowledge of chemistry, an architect could ascertain what was a good sample of oil, he would be conferring a great favor on the members of the Association and the profession at large. Another matter which he had been perplexed about was the presence of turpentine in paint, as to whether it had a deleterious effect.

Prof. Ellis said he could not give the desired assistance in regard to testing oil, but unfortunately the testing of oils was one of the most troublesome things a chemist had to do. Of course anyone accustomed to oil would be able to tell by its physical properties, and could form a very fair idea, but the chemical tests of oils were among the most awkward and troublesome things he had to handle. In regard to turpentine, he did not know of its having any injurious effect except as a diluent. Of course from a practical standpoint he knew less about these matters than his hearers, but what he understood was that the turpentine when it evaporated left the oil behind it in a kind of crystalline residue, leaving the paint in a form similar to the figures of salts left on a piece of glass when a solution is allowed to dry off. The term "crystalline" he did not of course use in its strict sense, and it was misleading, because oil is so very much removed from being anything like crystalline in its structure.

Mr. Langton asked if he was right in understanding that the fungi referred to could do no harm except where in addition to being damp it was also dark.

Prof. Ellis said they grew better in the dark.

Mr. Langton inquired if they would be likely to grow in a room such as that in which the convention was being held?

Prof. Ellis said they would in the centre of the timber.

Mr. Langton said that as the only object in painting wood above the cellar is to keep it from being affected by variations of dampness and dryness which make it warp and crack in an unsightly manner, in places where a few cracks are of no consequence as in the timber of a church roof, the best thing would be to avoid filling, and use water colours merely to disguise the discoloration of age, because otherwise one might be keeping in the dampness which produced the growth of the fungi.

Prof. Ellis said that as a general statement that was no doubt right. Spores would grow where it was damp, they would not grow where it was dry. The application of oil paints constituted a waterproofing, and if there was dampness in the wood before it was painted the painting would have the effect of retaining it there, but if the wood was dry and the coating remained impervious, it would keep dampness out.

Mr. Power said he thought a very good test of oil was to place a sample on a sheet of glass and leave it in a room at a temperature of about 68; if it formed a film, or dried in about twenty four hours it might be regarded as fairly good, and one might judge of its deterioration in quality by the time it took longer than that to dry. Another point was that an oil in which you had to put much turpentine was not a good oil. The older

the oil, the longer it had been allowed to stand, the more turpentine would be required to make it workable. The only object of turpentine was to make the paint flow, and where an excess of it was necessary for that purpose it was deleterious to the paint. He would like to know if Prof. Ellis would recommend ochre and oil as priming, the ochre to take the place of the commonly used red lead.

Mr. Aylsworth said he had gathered from what Prof. Ellis had said that ochre would be better than anything else for priming. In regard to the seasoning of timber his opinion was that kiln drying opened the pores of the wood more than the ordinary seasoning, and that when taken out of a kiln and put in a building it absorbed moisture. He believed this might be obviated if it were possible to lay floors in rooms already finished and warm. He knew of one instance where that had been done, and the floor was tight. Of course that was not practicable in the case of putting in flooring in a new building, where it would absorb moisture. He had heard carpenters say that they had made floors from green lumber cramped up tight, and that they would not open up as much as when made of kiln dried lumber.

Mr. Pearson asked if the pigment in paint did not assist as a preservative? In regard to the use of turpentine in paint, he had always had the impression that it produced blistering.

Prof. Ellis, replying to the questions which had been asked, said that what he had suggested was that there was more chemical union with red lead than with ochre, which caused it to dry faster, but which was the best paint he would not undertake to say. In regard to the blistering of paint, that was probably produced by the evaporation of the turpentine. In regard to the matter which had been discussed about the shrinkage of wood, especially the instance where the timbers had been taken from an old church and sawed up, he would suggest the possibility that wood which had been dry for a number of years was in a condition of strain, and when cut up yielded to it. He thought it probable that the effects referred to were due to some such cause as that rather than from any further change in the drying of the wood.

Mr. Gordon said he was sure all had been greatly interested and instructed by Prof. Ellis's address and the resulting discussion, and moved a vote of thanks to Prof. Ellis.

Mr. Dick had great pleasure in seconding the motion, which was carried.

Professor Wright then gave a talk on the Aspect Compass, illustrated by examples and diagrams, which excited much interest, and for which a vote of thanks was tendered him.

Mr. H. B. Gordon then read the following paper:

MUNICIPAL BUILDING LAWS.

The necessity for wise municipal building laws, efficiently administered, is evident to all who take an intelligent interest in building operations. Unfortunately, the enactment of such laws is generally delayed until gross evils are so multiplied that their efficiency is greatly impaired unless they can be made retroactive. Usually nothing in the way of sanitary supervision is attempted until long after a system of sewerage and water service has been in operation. Meanwhile many property owners ignorantly or unwittingly install in their buildings much that forms an unsanitary menace to the occupants and their neighbours. Generally, not until a severe fire has swept the central portion of some town, does it occur to its ruling authorities that some sort of building restrictions would be a general benefit. Possibly not till after the collapse of some building and the consequent loss of life, is the public conscience so awakened as to enact that the greed of speculators and the ignorance of architectural tyros must be subordinated to the safety of the people.

Very rarely, if ever, does the aesthetic sense of the voting public or their representatives, run the extravagant length of deciding that the nonarchitectural monstrosities proposed for the adornment of their streets, might be the better of a little intelligent revision by a competent public officer.

It therefore rests very largely with the members of this profession to impress upon the public the necessity for such laws; to urge their adoption in all our towns and villages; to seek their improvement where now existing; to loyally respect their requirements; and cordially co-operate in their enforcement.

Architects should remember that their natural desire for a free hand for themselves necessarily implies a free hand also for the speculator and jerry builder. Desirable building restrictions will not in any way hamper the operations of a true architect. The existence of wholesome regulations should be of great help to the profession in dealing with niggardly or unscrupulous clients. And no true man should want to override or set aside a law for the general good.

The scope of municipal building laws may be roughly divided into four branches, viz.:

1st, The safe constructional requirements.
2nd, The necessary sanitary restrictions.
3rd, Provisions against the spread of fire.
4th, Public aesthetic problems.

Some portions of such laws should be universal throughout the province; others must necessarily be determined by local conditions. A law or laws compelling the adoption of some of the general principles of safe construction should be provincial and general. The size and character of foundations to buildings, and the weights with which various soils may safely be loaded, is as applicable to the village as the metropolis. The thickness of walls in relation to their height and the weight of floors to be carried, is as necessary for the safety of life in the mill in the country as in the warehouse in the city. The safe load that may be imposed upon a beam or a joist does not vary with its urban or suburban position. The support to a superincumbent shop front is as important a problem in the village street as it is elsewhere. Indeed the necessity for some clearly defined building laws for small municipalities appears to be even more urgent than for larger places. In the former, the work is generally planned by those who lack theoretical knowledge of the strength of materials and the equilibrium of forces.

Fortunately there is a growing tendency in the smaller places towards the employment of trained men in the designing of their more important structures. But who that has observed the waste of materials on the one hand and the perilous experiments of skimping on the other, can fail to foresee the advantages of some plain general enactments that will guide and control all building.

Such a general law might well include the following, viz.: A statement of the safe sustaining power per sq. ft. of the various kinds of soil; an outline of the correct method of forming footings; a description of what must form the necessary kind of foundation walls, piers or posts under the various classes of buildings; the thickness and character of external and sustaining walls and piers; the strength of floor joists and beams; the sizes, kind and position of posts and beams carrying floors or walls; needful provision against wind pressure on high roofs, and other items of general safe provision; regulations for the repair or removal of dangerous buildings; general tables stating authoritatively the compressive and transverse strength of the commoner building materials; and the factors of safety to be adopted in their use.

There might also be a general classification of buildings according to their purpose and use, with special requirements adapted to each class; for example, churches and places of public amusement should be required to have ample provision for exit, and the stairs and passages proportioned to the audience. The floors of mills, stores and warehouses should be proportioned to carry much heavier loads than other structures. Provision against vibration in factories should be demanded. Regulations for the size and position of stairs in hotels and factories should be provided. Also general conditions to be observed in all buildings of certain classes that exceed a minimum height.

These suggested points, as well as others, might well be embodied in some general law; but pending such, it is clearly the duty of each municipality to protect the public by such reasonable restrictions. In addition to such general requirements each town or city may need special enactments for the public safety, such as regulation of the construction of light areas and their protection; points to be observed in utilizing the vault space under public sidewalks; the disposal of water from roofs; the protection of elevator shafts, and many other points.

Under the head of sanitary restrictions some laws might be made of general application to the entire province; while a more stringent law should be applicable to those municipalities having public sewerage and water supply.

A foul cesspit contiguous to a dwelling and but shortly removed from a well that supplies drinking water is a menace to health in the scattered village as well as in the more thickly peopled town. Unconsciously back venting a cesspool by a badly constructed drain from a country house, is quite as likely to produce diphtheria as an untrapped connection from a town residence to the street sewer. A filthy pan closet in a country hotel is quite as objectionable as its town cousin in a more pretentious hostlery. The abolition of privy pits and the substitution of a more sanitary contrivance is vastly more important in the village street where domestic water is drawn from the adjacent well, than in the more closely built town with its public waterworks.

In municipalities that are inaugurating a public water supply and sewerage system, the necessity is very urgent for the immediate enactment of sanitary building laws. Citizens who in their united capacity spend tens of thousands of dollars to provide such public conveniences should see to it that the benefits thus obtained are not neutralized by unsanitary drains and plumbing, and that their last state is not worse than the first. Nearly every town has its tinsmith plumber who proceeds to nullify the benefits of public sewers and water supply by ventilating the public sewer into the houses of his confiding patrons.

The general requirements of a sanitary building by-law are so well known as scarcely to require notice here: the correct alignment and trapping of all drains and soil pipes; the provisions for ventilating pipes and for preventing syphoning of traps; the material and character of all pipes used and the method of making joints; the class of fixtures allowed; the provisions for the efficient inspection of all parts and for the testing of the whole system. These and other points are well known to the practising architect and the city plumber. But alas, how limited is the knowledge and experience of the tinsmith plumber aforesaid, and his confiding patron; and how great the need for some explicit law to guide the one and protect the other.

Under the heading of "Provisions against the spread of fire," there is also much that might be of general enactment. It is surely as important for the country homestead to have a certain thickness of brickwork around its smoke flues and the chimney tops carried well up above the adjoining gables as it is for the town or city house. Negligence in the one case will likely result in the total destruction of the home, while in the other, a timely visit from the neighbouring fire engine may extinguish the blaze before much damage is done. One can hardly understand how a village or small town that spends thousands of dollars in the equipment and maintenance of a fire brigade, does not make the first effort to prevent the recurrence of serious fire risks by passing a suitable building law. Nor is the action of the authorities of larger places much more intelligent. We have the example of a large city, after very destructive and repeated fires, neglecting the advice of a committee of architects who pointed out at length the the amendments of the law necessary to check a recurrence of the disasters.

The amount of money lost by fires in one year in Ontario, is enormous, and much of that loss is attributable to negligent and unscientific building operations. The unthinking may pass this over by remarking that the insurance companies pay the most of the loss, and that an occasional fire is necessary to keep up the peoples' interest in insuring. They forget that the insuring public have to pay the whole, and that insurance rates bear at least some proportion to the risks run and the loss sustained.

Some look to the insurance companies, to demand better building regulations, and no doubt they might do much in this direction. Their action in making their rates bear some relation to the efficiency of the fire brigade and fire extinguishing apparatus of a town, has quickened the movements of many a Council. Were the same pressure brought to bear in insisting on the enactment of rigid building by-laws, many a town councillor would awake to his duty in this respect. Some who have given this subject much thought, advise that the insurance companies classify buildings more definitely, and rate them more distinguishingly in regard to the material and manner of their construction.

The movement is in this direction and it is helpful to the architect as well as his enterprising client. But the usefulness of such a distinction is much curtailed by the character of surrounding buildings which may have been put up regardless of the fire risks they contain.

A general law for the whole province might cover such matters as: the manner of building chimneys, hearths and fireplaces; the location, protection, and isolation of steam boilers, furnaces, forges, etc.; the insulation of hot pipes, the proper disposition and insulation of electric wires; the isolation of buildings containing extra hazardous contents; special regulations concerning the construction of theatres and other places of public amusement. And it would be well to have the erection of all hotels over a certain height, no matter where built, subject to some clearly defined rules of construction for the prevention or slow spreading of fire. It seems only reasonable, that everywhere, those who wish to build within a certain limit of the boundary of their property, should be under some restrictions, so as to prevent them creating a serious fire risk to endanger their neighbours' property. In towns and villages as well as in cities there should be some limitation as to the class of buildings allowed on the more thickly built streets.

Each city and town will require much more in their by-laws regarding fire protection.

The local conditions will largely determine whether the division of a town into zones in which the restrictions are graded, is desirable or not. The majority of important American cities make no distinction. As a tentative measure it is probably desirable in our young and scattered municipalities.

The central business and crowded part of a town requires more stringent regulation than the outlying districts. All parts however should be under some governing regulations, as it is foolish for any town to have a zone in which people can do as they like in the matter of building.

Some limit should be placed on the external use of wood, and the size and location of wooden sheds and stables should be regulated.

It will be found that even in the residential parts of a town, a fairly stringent building law will work for the ultimate advantage of the locality. "Brick buildings only," is not a severe restriction when their continued preservation is considered.

The kind of roof covering that may be used is an essential matter. The rapid spread of fires is largely attributable to the inflammable nature of the surrounding roofs. Wooden dormers and cornices are another prolific source of danger, and their construction and covering should be restricted or regulated. The size and description of party walls and of parapets above roofs are questions for necessary legislation, as many a serious fire has been checked by efficient walls.

The structure of stairs and their surroundings should be safeguarded with wise restrictions, not only to prevent the rapid extension of fire, but also for the safety of life.

The enclosing walls of elevator shafts are deserving of much more attention than they usually receive in building laws.

Special restrictions are desirable for all buildings over a certain height, so that they may not prove towering fire giants, to spread brands of destruction in every direction. It is regarded by many as only right, that all buildings over a certain height should be built as fireproof as modern conditions will allow.

In defining the special requirements for the different classes of buildings, it is desirable to have a classification with accompanying definition clearly setting forth what is intended by buildings of a certain class.

The following six fold division is suggested:

1st. Public building class, including all places of public assembly, that have audience rooms capable of seating more than a certain limited number.

2nd. Hotel class, including hospitals, asylums, and lodging houses accommodating more than a certain number.

3rd. The Manufactory class.

4th. The Warehouse class.

5th. The Office Building class.

6th. The Dwelling House class.

It will occur to all that structures of the public building class require special regulations for their construction and maintenance, that the audiences may be protected in case of fire and panic.

Buildings of the manufactory class, as well as the hotel class, should have stairways protected from rapid firing, and suitable fire escapes easily accessible.

The restriction of the undivided floor area of warehouses and factories is a wise measure, provided that exception is made in favor of buildings constructed on so called fire proof or slow burning principles.

Building by-laws should contain clauses dealing with the question of repairs or alterations to existing buildings. These should state the percentage of value of allowable repairs to old structures that do not comply with the by-laws; and the basis of valuation from which this percentage is to be determined.

By-laws can only be made definite and explicit by containing a glossary of the terms used throughout their enactments. The importance of this is evident to all who have had to interpret building laws.

How essential it is to have a clear statement of the datum line from which the height of walls or buildings is to be measured, to know just what is intended by first story, and what is a basement and what a cellar; to be sure that your idea of the maximum or minimum height of a story will not conflict with that of the official administering the law; to know what is meant by bearing wall, division wall, party wall and partition wall; to solve the seemingly simple question of what constitutes a mansard roof; to have settled without cavil, what is mortar? what is cement mortar, and what is cement? and even to be informed which ton is meant when such weight is mentioned.

It is when we consider the last or aesthetic side of building laws, that debatable ground is fully entered. Here unartistic democracy puts down its foot and forbids further restriction.

The abstract aesthetic question of having the fronts of all houses in a line at a certain distance from the street, arouses no enthusiasm. But let a concrete case arise where some selfish men obtrude their buildings so far forward as to thrust their neighbours into obscurity, and those who suffer are likely to be interested in a proposed remedy.

The public may not appreciate the beauty of curtailing the height of buildings to some proportion to the width of the street upon which they are built; yet they might apprehend the justice of not allowing some men to completely overshadow the light and air of their neighbours.

If people will tolerate unsightly projections of signs, oriels and cornices, so long as it is merely an aesthetic question, possibly they may protest that space belonging to the public is occupied by private parties.

Ordinarily men do not care to be tied to a building line or allow some of their property to be regarded as a boulevard, but who that has visited Washington and other cities, where such regulations are in force, can help being impressed by the result.

It is only by comparison with what has been done elsewhere, that we can educate the general public to a sense of the needs at home.

What would have been the result if each of the architects of the Chicago World's Fair buildings had been allowed to work his own sweet will without a concerted action or critical oversight, may be left to the imagination. What they did accomplish under wise restrictions as to height of cornice line and general style of design, the Court of Honor bore witness.

Possibly we may never reach the aesthetic status of some continental cities where the street front architecture on important boulevards is subject to the approval of a public official; but the enactment of some effective, if less stringent by-law in this direction, should be the desire of all lovers of architecture.

A building by-law would not be complete without some regulations to be observed during the erection of buildings, such as, the proportion of the public street that may be occupied by building materials; the protection and convenience of the passing public by covers and sidewalks; the height and manner of scaffolds abutting on the streets; the protection of open areas and excavations; the erection of temporary sheds, engines, etc.

Any by-law, however complete, will be a comparative failure without efficient administration. So secure this a really first-class man must be appointed as inspector of buildings. Only such should be appointed to this important position to protect the lives and property of the people and oversee so much that tells for the safety, comfort and enjoyment of the masses. To get the right man in the right place is often a difficult matter when the reach of aldermanic influence is at work. The one who is really competent will not seek the office. The position ought to seek him.

Some one ought to be appointed, who besides a practical experience in the supervision of buildings is competent to make the necessary examinations, calculations and decisions both theoretical and practical in all matters pertaining to the by-laws. He should be a man incorruptibly above reproach, and while courteous to all, firm and just in administering the spirit of the law. Such a man should have discretionary power to modify the provisions of the by-law where there are practical difficulties in the way of carrying out the exact letter of the law, so long as the spirit of the law is observed, the safety of the public secured and substantial justice done. His duties should include the examination of the plans and specifications of all proposed buildings, to determine if the contemplated work is in accordance with the building by-laws; the granting of permits for the execution of such work; the examination as often as practicable of all buildings in course of erection; the examination of all buildings reported as dangerous; and the prosecution of all who infringe the by-laws.

A permit should in all cases precede building operations, and to obtain it a copy of both plans and specifications should be filed.

The specification is necessary to inform the inspector of the character of material and the method of construction. The filing of both plans and specifications is essential for reference as the work proceeds. By the sun print process copies of the plans may easily be supplied. Architects should not grumble at such extra trouble, as they will doubtless find that such requirements tend towards their being more frequently employed.

The foregoing suggested points, together with much that naturally accompanies them, when properly amplified, clearly stated and systematically arranged, should form the basis of municipal building laws.

They may serve to point out the desirability of enacting building laws in small towns and even villages. They may suggest some necessary amendments to existing by-laws in other places, and may convey some ideas favourable to the passing of a provincial act.

If their perusal stimulates the members of this Association to active efforts for the improvement of building

regulations, this short paper will have served a useful purpose.

Prof. Wright at the conclusion of the paper said that while this paper is intended to deal mainly with the fire by-laws, in the early part a reference is made to a factor of safety which should be extended, especially with regard to wood, as there are apparently conflicting ideas before the profession. On the one hand we have a factor of safety of two regarded as sufficient, and so long as the views of the author are observed fully it is perfectly safe, but if this factor is applied to the results of the determinations of the modulus of rupture from other sources it is not safe. This might be explained in this way on the one hand we have a low modulus of rupture with a low factor of safety, giving the same working fibre stress as the higher modulus with the higher factor. This low modulus of rupture above referred to has been obtained by basing conclusions on the results of experiments which are generally rejected.

Again, it is well before using the results of any experimental research to observe fully the method under which such determinations have been conducted. For instance, after an elaborate set of experiments Prof. J. B. Johnson has established a relation between the percentage of moisture in a beam and its strength. So that having given the strength of a beam and its percentage of moisture it is possible to calculate what its strength would be with any other percentage of moisture. You will find these results and others equally valuable published under the direction of B. E. Furnow, by the U. S. Department of Agriculture Division of Forestry. These results, you will find, are very extensive and reliable and are the most advanced determinations of modern scientific research.

I should like to say a few words on that much vexed question of Portland cement. At the outset let me say that most architects and too many engineers draw up elaborate specifications regarding Portland cement and accept the material from the manufacturer without any examination as to its qualities whatever. Now from the very nature of the process of manufacture this material is liable to very great fluctuations, and for that reason alone it requires careful watching to say nothing of the danger proceeding from middlemen who are willing to doctor the cement for a few paltry dollars. I have examined within the last year several large shipments which were absolutely worthless simply so much sand, or worse still, containing a large proportion of lime. These shipments of course were condemned, but you may feel sure they found their way into work where no examinations were made. Now I suppose the reason this neglect of testing is so general is because you have been led to believe a laboratory with a full equipment a necessity. While this may be true as far a thorough knowledge of the material is concerned, yet you may find out a great deal in a very simple manner. If you would mix a small quantity of cement with water and after it is set place it in hot water at a temperature of 110 F. if at the end of 48 hours it remains solid, adheres to the glass and keeps a sharp edge, you may feel fairly sure that it will not go to pieces on the work. With a small pair of scales and a fine sieve you could easily determine the fineness of the grinding. A cement which would not fail on glass in hot water and was fine, leaving only a small residue, might with safety be regarded as a fairly good cement. If in conjunction with this you determined its tensile strength you would be quite safe in your opinion.

The discussion of Mr. Gordon's paper was then proceeded with.

Mr. Gordon suggested that a resolution should be passed something to the effect, "That this Association, being impressed with the desirability of having some general building law applicable to the whole province, and also local and municipal building laws for each town and city, resolves that a standing committee of five members of this Association be appointed by this convention, with instructions to formulate a general enactment of such desirable building laws, and that the committee correspond with architects and others of kindred professions in the various towns and cities to secure such co-operation as is possible for attaining this object." He begged to move that resolution, and thought it very desirable that the project should be attempted.

Mr. Burke seconded the motion.

Mr. Dick pointed out that while there was danger, on the one hand, in allowing too much latitude, leaving people to do as they choose, and incurring thereby danger both constructive and sanitary, yet, on the other hand, there was danger of going too far in the direction of paternal legislation, by making the building laws deal so much with detail that they would almost take the place of a building hand-book, and put it in the power of people to say that where so much was determined by law there was no necessity for skilled architects. Of course all knew that building by-laws, or any other kind of laws, would never make architects in the true sense of the word. If building by-laws were made more strict than was absolutely necessary it had a tendency to deter people from building, because building was done generally as an investment, and if the cost of building was made excessive so that the returns from a building would not pay interest, capital would be chary of going into building operations.

Mr. Power quite agreed with all Mr. Dick had said, especially that the matter of legislation in that line might be overdone.

Mr. Gordon explained that he quite agreed that it was necessary to act with caution and discretion in regard to this matter. But at the same time he thought the Association ought to take the initiative in devising some active means of remedying the evils which existed. There were municipalities in which people were alive to these evils, and were endeavoring to cope with them, and who ought to be assisted in their endeavours. These people did not know just how to proceed, and had not the knowledge to enable them to grapple successfully with this problem, and there ought to be some committee to whom they could apply, and therefore he wished to see this committee appointed. It was the duty of the Association to educate public opinion in these matters, and that could be best done by appointing a good strong committee to exercise their judgment in regard to the matter. He thought such a committee would have enough common sense to avoid the evils which had been mentioned, and to know that the same law which was applicable to Toronto would not be adapted for some little village or town.

Mr. Dick stated that he did not for a moment intend to raise any opposition to the appointment of such a committee, on the contrary he was prepared to vote for the adoption of Mr. Gordon's resolution.

Mr. Power also stated that he did not for a moment question the correctness of what Mr. Gordon had said, and he was in the same position as Mr. Dick.

The President did not think there was any danger of any such legislation as that suggested being carried too far, for the most they could hope for would be that a very small portion of their recommendations might be adopted. How far we should go, he thought, might safely be left to the committee appointed.

The resolution was then carried.

The election of the members of the Council was then proceeded with, and resulted in the election of Messrs. Burke and Lennox, of Toronto, and Mr. Power, of Kingston, as the three new members of the Council.

Mr. Langton then moved that the thanks of the Association be tendered the Hon. the Minister of Education, for permitting the use of the School of Practical Science in which to hold the convention, and to Professors Galbraith, Wright and Ellis, for their very kind assistance in making the convention a success.

Mr. Burke having seconded the motion, the President tendered the thanks of the Association to those of the gentlemen named who were in the room, stating that if half the members of the Association would help as heartily as those gentlemen had done, especially Prof. Wright, the conventions would be even a greater success than they had already been.

The convention then adjourned.

FLYING SHORES AND BUTTRESSES.

[COMMUNICATED.]

THE present condition of the architectural profession may be briefly and prosaically stated thus: It comprises all those men who design and superintend buildings and a large number of others whose business consists in the ordinary transactions with reference to house property and valuations. In fact, the field is so varied and extensive, as though the knowledge necessary to befit an architect was only of secondary importance, and left the holder of this title ample time for study and the practice of other businesses and professions that are in a measure connected with it, that we find many styling themselves architects, valuators, civil engineers, sanitary and ventilating engineers, etc. Architecture is a profession that can hold its own without the support of all these flying shores and buttresses. It has always appeared to us to be a feeble method to adopt to strengthen their position and to ensnare the unwary client with these high sounding and empty titles.

Upon what ground do these men lay claim to these titles? There is no law in the land to prevent a tinker claiming that he is a ventilating engineer as far as that goes, but an architect, if he is an architect, has made a study of it, and is supposed to have some knowledge of these branches of the building trade with which he has to deal. "Ye cannot serve God and mammon." If a man is an architect he is but a poor civil engineer, and vice versa. Surely if a man wants to employ an architect, he will go to an architect if a civil engineer, to a civil engineer not to a weak admixture of both.

Apart from the time and study necessary to obtain any degree of competency in either profession, art in architecture and art in engineering, although they are both ultimately striving for the same goal, have each to make concessions one to the other before the happy combination may be reached; and this result will never be obtained by these half-masters of both and master of none.

There are monopolists in commercial life, and some of these monopolists have proved successful, but we fear these aping professional monopolists will fall to the ground between so many stools.

There is one other buttress that occurs to us, that these professional monopolists have overlooked; Why not Architect and Solicitor? There would be just as much sense in assuming this as in assuming the others, for in the practice of the profession legal difficulties sometimes occur—questions of boundaries, of ancient lights, rights of way, of conditions of contract, and of many other kinds possible present themselves. We make no question but that this buttress would also have been seized upon had it not been that the law is a close profession.

What are the duties of an architect, that these gifted individuals have mastered and found time to study and make themselves expert in other professions? In judgment he is expected to be a better mason than a man who has spent all his life in working stone, a better carpenter than a man who has handled lumber all his days, a better plumber, a better plasterer, a better painter, a better glazier, etc., than anybody who has devoted his life to any one of these particular trades. This is only a small part of what the public looks for and expects from an architect. He might be proficient in all these branches and yet be no architect at all, for his primary business as an architect is not merely to know, but to place, to invent, to adapt, to be incessantly conquering fresh difficulties, not by lavish outlay, but economically, gracefully, and in a refined manner. That these architectural difficulties are conquered in this way is the exception rather than the rule when we take into consideration what an architect is expected to know. To-day he is called upon to build a bank and he must make himself familiar with every detail of the banking business; next week he must make himself perfect in all the knowledge pertaining to tanning, and a month later he must enter heart and soul into the manufacture of bicycles. All this he has to do, not as a barrister has to do it, just far enough and deep enough to talk about it plausibly to convince a judge and jury, but in a way that will stand the test of practice and of fact. His bank must be arranged so that every facility is offered to clerks and public on the most economic principles; his tannery must be capable of turning out real leather, and his bicycle factory arranged with all the latest improvements with no waste of space or labour. Then the man who builds churches or private houses has not only the practical questions of convenience to deal with, but the whole world of architecture as an art besides. When he is familiar with all trades, expert at all sorts of planning and arrangement, he is next expected to add to all this knowledge and all this skill as much artistic faculty as would by itself make the fortune of a painter and sculptor. For this artistic faculty a liberal public never dreams of paying him. It generally offers him the same percentage for building churches as for building cow-sheds, and cannot repress its astonishment when its churches are not built with the perfection it desires. It is also an imperative necessity that the style he adopt for his building should be that which every spectator prefers, since anyone who is not pleased will assuredly lay the fault on the architect's want of ability rather than on his own want of judgment.

The conduct of the works is equally simple, as all that is required of him is that he should be able to answer at once every question that is addressed to him and to decide definitely there and then the best mode of procedure. In his supervision of a building, all that is needed is that he should be omnipresent. Every one who is employed feels that it is the architect's business to watch him, and if he can scamp a bit of work without detection it is on the architect the real shame and disgrace of it all will be. The architect ought to have been here and everywhere at once, and then such things could not have happened. Still the architect's duties are not yet ended. The builder's accounts still remain to be made up. Every item which he did not foresee before the agreement was signed rises up against him as an accusing extra; every detail which he revised and re-revised to make it more perfect does the same; every day which he spent at his own cost improving points of planning and construction, does the same; and now instead of being thanked for his care and thought, he is blamed for having kept the building back and running up a bill of extras. These extras must now be gone into in detail, all the deductions and additions measured up in the manner of measurement peculiar to each trade, and the architect must know to the fraction of a cent the value of each particular item, and these claims must be finally adjusted to the satisfaction of the client and contractor.

Time and space fail us to enlarge on the multifarious duties imposed on the architect, but the foregoing remarks will enable us to form some idea. As was before stated there is sufficient ground to cover in the field of architecture without monopolizing an expert knowledge with other businesses that have an indirect connection with architecture.

What argument could prove a stronger incentive to the profession at large, than this, to put forth every effort to obtain the passing of the Act when the word Architect shall have a recognized standing. Then all these flying shores and buttresses that have been found necessary to bolster up the profession may be dispensed with. The course of study then prescribed will embrace those branches of the building trade in so far as they are necessary to an architect in the exercise of his profession, and it will be then only after several years of hard work and close application and an applied test that one can assume the honorable title of Architect, and there will be no further need of this arrogating of empty titles which every Tom, Dick and Harry can assume.

The annual meeting of the Standard Drain Pipe Co., of St. Johns, Que., was held on the 13th inst. Mayor Trotter was re-elected president and Capt. Coursol, vice-president.

The Prismatic Glass Co., of Toronto, are manufacturing a new and meritorious article for pavement lights, extension sky lights, illuminating ornamental windows, etc.; particulars of which will be found in our advertisement pages. The Company have recently sold 5,000 pieces of double prism sidewalk lights, amounting to five tons of glass, for use in the new Ogilvie Building, Montreal.

FIRE RESISTING STRUCTURES.

THE destruction of the Manhatten Bank building in New York has directed attention to a weakness in the steel skeleton structure, and has shaken faith in the fire resisting qualities of such buildings. A late fire in Chicago, in which two similar buildings were demolished, has further called attention to the matter. It is established that in such buildings, even if the material will not burn, it will warp with the heat to such an extent as to bring them down, and that although the iron work may be covered with a fire resisting material absolute protection is not guaranteed. In the case of the Manhatten bank building it should be stated, however, that the floor beams were not completely covered with the fire-resistant, the lower edge being flush and only protected by the plaster finish. The building was erected some years ago and previous to the passage of the regulations on this point now in force.

As a result largely of their experience at these two fires, Chiefs Bonner and Sweenie, of the New York and Chicago fire departments, have declared these tall sky-scrapers to be huge fire traps, especially when their contents run largely to inflammable materials. They pronounce in favour of buildings of brick and yellow pine. In such the fire burns more slowly, and there is better chance of saving the contents. The opinions of such men should carry much weight. It seems probable that the insurance companies will advance the rate on such buildings, in which event the greater premium will be a serious tax on their income and increase the expense of tenants, making that class of building much less desirable as an investment.

THE LATEST.

The Prismatic Glass Company,

OF TORONTO, Ltd.

Manufacturers under "PENNYCUICK PATENTS" of all kinds of

Prismatic Window Glass

and Double Prism Sidewalk Lights.

Isn't it Better?

to get the best at first than to "put up with" or have to tear out a poor and unsatisfactory heating apparatus.

OXFORD

Boilers and Radiators

For Hot Water or Steam . . . .

Always give perfect satisfaction

They are made in enough varieties of size and style to suit the loftiest public buildings, or most modest dwellings, equally well.

Their mechanical excellence represents 52 years of experience and experiment. We are satisfied that these are the best Boilers and Radiators that money can buy.

Send for our Catalogue; our prices are right.

CANADIAN ARCHITECT AND BUILDER.

VOL. IX.—NO. 3. MARCH, 1896 PRICE 20 CENTS $2.00 PER YEAR.

—THE—

CANADIAN ARCHITECT AND BUILDER,

A Monthly Journal of Modern Constructive Methods.

(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD).

PUBLISHED ON THE THIRD THURSDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

C. H. MORTIMER, Publisher,

Confederation Life Building, - TORONTO, CANADA.

Telephone 2362.

Branch Office: NEW YORK LIFE INSURANCE BUILDING, MONTREAL.

Bell Telephone 2299.

SUBSCRIPTIONS.

The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.

Prices for advertisements sent promptly on application. Orders for advertisemnets should reach the office of publication not later than the 12th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of technical value to the persons in whose interest this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publisher of any irregularity in delivery of paper.

TO ADVERTISERS.

For the benefit of Advertisers, a copy of this journal is mailed each week to persons mentioned in the CONTRACT RECORD reports as intending to build, with a request to consult our advertisement pages and write advertisers for material, machinery, etc.

The O.A.A. Act.

It is pleasing to note that the press, with few exceptions, speak favorably of the proposed Bill to amend the Ontario Architects' Act." Indeed it is not possible to understand how any well-meaning citizen can object to the proposed amendments, as they do not in any way interfere with the rights of any individual or prevent the public from taking advantage of the knowledge or skill, or both, of anyone practising architecture who may not be licensed under the Act. The Toronto World, while favoring the amendments, thinks there is a weakness in the Bill, inasmuch as it does not provide a designation for the unlicensed practitioner. "If he is not to be known as an Architect how can he designate himself?" It can hardly be expected that he will be obliged to solicit business as an "Unregistered Architect," or that he will have to follow Webster and advertise himself as "a person skilled in the art of building." Evidently The World has not read the proposed Bill, or its "funny man" has taken advantage of the staid editor's absence. The unlicensed practitioner, according to the provisions of the Act, may designate himself whatever he chooses, so long as he does not call himself an "Architect." He may be an "Architectural Draughtsman," a "House Designer," or he may advertise himself as "The Greatest Plan Preparer of the Nineteenth Century," if he so wills it. In fact, there is no limit to designation. Here is a sample which may be found in a newspaper published not over a hundred miles from Toronto: "John Roe begs to inform the public that he is prepared to take all kinds of contracts for buildings, repairs, or furnishing materials for same. Plans and specifications for churches, stores and all other kinds of buildings, furnished on the shortest notice. Estimates given while you wait. P.S.—If I get the contracts I make no charge for plans. Sash, doors and blinds always on hand. Live and let live. Give me a call." This, we think, is broad enough a "designation" to cover The World's objection, and the Bill proposed does not pretend to interfere with John Roe or his business. The public will eventually be the gainer if this Bill becomes law, not only because it will have some guarantee that the person intrusted with its work will be in a measure fitted for it, but because of the very fact of a license being required to practice, will prove an incentive to the aspirant for the public favor to better qualify himself for the expected work, knowing as he will know that he will meet in competition men of his own profession, whose knowledge and

experience cannot be gainsaid. It may take a number of years after the passing of the Bill before the architectural profession will feel any direct benefit from it, but much benefit must come sooner or later in many ways. It will have a tendency to create specialists in many branches of the science, just as they have in Europe. One man may become an authority on Gothic, another on Classic, while a third will be known as an oracle on the Renaissance. Ontario is sufficiently advanced in wealth and artistic requirements to give ample scope for specialists in every department of architecture, but in order to attain eminence in any one of them the profession must be protected so far as the public interests will permit.

The City of Toronto v. Neelon.

Mr. Neelon's action against Mr. Lennox, architect of the new city buildings, and the City of Toronto, to recover damages for alleged wrongful dismissal from his position as contractor for the work, has been argued in the Supreme Court. The verdict of the Court confirms the decisions of the inferior Courts, which, as our readers know, were adverse to Mr. Neelon's claims. The case will no doubt be carried to the Privy Council, but there would now seem to be little reason to expect a reversal of the decisions of the several Courts through which it has already passed.

The Late Mr. Atwood.

Mr. Chas. B. Atwood, well known as one of the architects chosen to design some of the more prominent buildings at the World's Fair, died at his home at Buena Park, Chicago, Dec. 19th, after a short and painful illness. Mr. Atwood had a wide reputation in the United States as an architect of more than ordinary ability. He followed, to some extent, the lines laid down by the late Mr. Richardson, to which he added much that was his own, and which evinced originality and scholarly thought. His best works at the World's Fair were the Art Palace and the Peristyle, two buildings that were much admired by members of the profession who had the pleasure of seeing them. Mr. Atwood was born in Boston, Mass., forty-six years ago. He went to Chicago in 1890 and entered into partnership with D. H. Burnham, the eminent western architect, and was a member of the firm when he died. He was unmarried, "for," as he told the writer on one occasion, "if I was a married man my duty to my family would prevent my giving to my profession that attention I wish it to receive at my hands." He loved art, for art's sake.

Dangerous Structures.

The necessity of restricting the practice of architecture to persons properly qualified for the work was exemplified by an accident which took place in Toronto recently. The occupants of a warehouse, while engaged in loading the upper storey of the building with merchandise, observed that one of the doors on the ground floor would not close. They called the attention of the owner of the building to the fact, and he in turn brought the matter to the attention of his architect, and requested him to make an examination of the building and to estimate its strength. The result of the architect's examination showed that, allowing for the usual factor of safety, the building was barely strong enough to support its own weight. Yet, in ignorance of this fact, the occupants had placed a load of 20 tons on one of the upper storeys, and were proceeding to add to this load, when they fortunately made the discovery which resulted in the architect's examination. The building in question is an old one, and was put up in the days when no accurate methods were employed to ascertain the strength of structures. The supports of the upper floors are 7¾ inches in diameter while those of the first storey are but 7 inches. There are, no doubt, a large number of such structures in use throughout the country, and it is too much to expect that sooner or later a disaster will not result.

Roof Construction

An accident occurred on the Thursday night following Christmas that might have resulted seriously. An entertainment was being held in the Mariners' Bethel Church, Philadelphia, when a heavy gale of wind lifted off part of the roof and scattered the fragments on the grounds below. A panic ensued; but, owing to the coolness of a few no one was seriously hurt. Within the last few years many buildings public and private—have been unroofed, a condition that ought not to be possible if proper constructive methods were adopted. A roof should be so secured that its displacement could only take place with the disruption of the walls, or the building itself. Like many prevalent maladies, the unroofing of buildings seems to be altogether a modern scourge. If any buildings were so constructed in ancient or mediæval times that their roofs were blown off or destroyed by a collapse, the events were kept very quiet, for very few accidents of that sort are mentioned by the older writers. In fact, if the old builders constructed their roofs on the same lines as the examples that have come down to us from the early centuries, there was little danger of their blowing away or collapsing. The roof of Westminster Hall, apart from its ornamentation, is a solid example of fine constructive cunning, and its attachment to the walls such that divorce is rendered impossible without causing the total destruction of the latter.

Lien Laws.

Mr. Dowling, Labor Commissioner of New York, has been investigating the lien laws of that State, and in a letter to a Syracuse paper states that the laws as they now stand "are of no benefit to either the working man or the owner of the buildings." Mr. Dowling has made a study of the lien law for ten years, both in his own and other States, and the fact that he has arrived at the opinion that these laws are of no benefit to either workman or owner, is a matter that deserves consideration. When lien laws were first enacted, they were intended solely and altogether to protect the workman, to place in his hands, as it were, some means by which he would be sure to get his wages. All this was right and proper, but subsequent amendments and additions to the law, enabling material men, contractors and sub-contractors to file liens and collect on them, have nullified whatever good there may have been in them at first, and so complicative and irritative have they become that many men decline to build for fear they may get entangled in the meshes of the law. In Ontario the law, as it now stands, is actually a deterrent to progress and should be stripped of all its excrecenses and rendered as simple as possible. No claims should be allowed under a lien, other than actual labor done by day's work. A liberal percentage of the contractor's tender should be held by the owner as now, for labor only, and this amount should be exempt from all other claims until labor is satisfied or the amount exhausted.

Australian Architecture.

Many people have an idea that our brethren of Australia are far in the rear of us in the way of building. This, however, is a mistaken idea, for Melbourne and Sydney contain as fine buildings, public and private, as can be found anywhere on this continent. The Eastern Market Building in the city of Melbourne is said to be without a rival anywhere for beauty of exterior, adaptability and general convenience. For several years the municipal authorities of the rival city of Sydney have been collecting data for use in designing and building a new market for that city that would excel the famous market of Melbourne. The result is that an immense Renaissance structure is to be built, on which a central dome will rise to a height of 150 feet above the sidewalk. The contract to complete the building has been let for the sum of $1,250,000. The designs for this mammoth building were prepared by Geo. McRae, city architect, Sydney, N.S.W.

Building Timber.

The gradual disappearance of good building timber from Ontario, and the substitution of hemlock, soft elm and basswood for white pine and the better class of woods, is the cause of much wrong-doing in the building trades, and the creation of a class of buildings whose lives will be short by comparison. The high price of white or red pine joists is made an excuse by country builders, to substitute hemlock instead, where the use of such uncertain lumber should be carefully eschewed. Fancy hemlock joists in the lower floor of a country farm house, where perhaps only a few inches of space exists between the damp earth and the lower edge of the joists. What is the result? A rotten floor in a few years, and a miasmatic one from the moment it is laid. Where it can be avoided, hemlock should never be employed in a situation subject to alternations of dryness and dampness. It does very well if kept constantly dry, though it has the quality of becoming very brittle if made very dry, and is not by any means a reliable wood if subject to sudden strains. Hemlock may be used with profit in the upper floors of small or medium-sized buildings, that are not likely to be subject to heavy work, and when once in place and properly secured, do satisfactory service. For inside studding, scantlings and light roofing timbers, it will do fairly good service if skilfully arranged and properly secured. It must not be supposed that we decry hemlock as a building material. We do not. Like everything else it has its uses, and it is its improper use we object to. For rough boarding, sheeting and roof covering hemlock has no equal. It is superior to pine in nail-holding qualities, and when dry and properly machined makes a firm and solid base to "side" or shingle over, and each nail may be driven home with a certainty that it will stay where put. When covered, as under shingles, hemlock is not so likely to "swell" or "warp" in a damp atmosphere, as pine would under like circumstances. Hemlock timber, though frequently used in heavy constructions, is rarely satisfactory, owing to the unequal direction of the grain, and the difficulty of working it to correct and proper shape. While it may do passably well for temporary structures, such as bridge centres, platforms, scaffolding, etc., it should never be employed for outside purposes where permanency is an important factor. The scarcity of good lumber, or rather its high price, is working favorably in the interests of permanent buildings. Few country people in the well settled districts of Ontario now ever think of building their houses of wood altogether. The old-fashioned frame house gave way to the lighter and more compact scantling or "balloon" house, and this is fast giving way to the "cased" or "veneered" house, or the solid brick house. It is beginning to be known that a house built of bricks costs but little more than a house built altogether of wood, while the life of the former is three times longer than that of the latter, and the former needs no paint on the walls to preserve it, or to prevent the "poverty stricken" appearance which is sure to attack the latter once every four or five years. The advent of the brick house in the country should be encouraged, and whenever the designing of these is placed in the hands of an architect, he should employ every possible means to give his work a "truly rural" but effective appearance.

An Uniform Size for Brick.

The variation in the sizes of bricks made by different firms often leads to a great deal of inconvenience and useless labor and expense. The introduction of pressed bricks or terra-cotta bricks, among common moulded bricks, is often prevented because of the unequality of sizes the pressed brick generally being much smaller than the moulded ones and this militates against the interests of pressed brick makers, for, if moulded and pressed bricks were of one uniform size throughout the country, the use of pressed bricks for trimming windows, doors and other openings, would soon become a fixed practice in the smaller towns, villages and country, and the practise has much to commend it from more points of view than the artistic one. It seems to us that it would be as much within the scope of parliamentary limits, to legislate on the question of "uniformity of size in bricks," as it is to legislate on "weights and measures," and the rights of the community are nearly as much concerned in one as in the other. If one brick differeth from another one-twentieth of its size—and there are greater differences than this—it means a difference of five brick in each hundred, an item that becomes formidable in buildings requiring five or six hundred thousand bricks. Even in a much smaller building the difference may make or unmake the contractor. True, architects frequently specify certain makes of bricks, but this custom is not to be recommended as it may lead to abuses, therefore it is better for everyone concerned that the contractor have a free hand in purchasing all his material, providing always the standard of quality is maintained. A practice, quite common with our neighbors to the south, is to specify certain "makes," not only of bricks, but of hardware, paints, plumbing fitments, heating apparatus, and other building requirements, in all specifications; in fact, in many of the printed forms of specifications, certain goods are specifically named, and the contractor is not permitted to use any other. It will readily be seen to what this method may lead, and does lead—and how the owner may have to pay for goods of an inferior sort when the quality might have been obtained for less money. It is well enough for an architect to specify certain brands at a given price, and to see that the price is paid; then the owner gets value, and the contractor "knows where he is at."

DOMESTIC ARCHITECTURE.*

By Grant Helliwell.

In venturing to offer a few remarks on this subject, I do so not with the hope of being able to present anything but what has, in substance, often been stated before. The principles on which domestic or any other kind of architecture are based, never change. They are the same to-day as when the first constructions of man worthy of the name of architecture were built. But the applications of those principles are ever changing, and will continue to do so as long as man continues a builder.

This fact renders apology needless; moreover, apart from the deeply absorbing interest with which the subject is invested on its own account, it must ever be a living question with architects, since in the very nature of things, the larger part of the average architect's own living is directly connected with it.

Domestic architecture may very well be considered in two aspects, the first general and the second specific or individual. The former may be likened to the case of a man, who, from some eminence looks out upon a scene of Nature's making. As his eye travels over space, trees, hills, valleys, brooks and ponds, all combine to form a scene of beauty charming alike to vision and to sense. The second aspect is likened to the same man, who, having descended from his vantage ground, concentrates his sight and attention on the foliage of some specific tree or the entrancing beauty of some particular flower. This little analogy, however, is only relatively correct as it must be admitted that the architectural achievements of man seldom if ever bear a favorable comparison with those of Nature's architect.

Taking up then our subject in its general aspect, the impression produced on the mind of an observant person by our residential architecture depends largely, not only on the buildings themselves but on their approaches and surroundings, the disposition of trees and shrubbery and the arrangement of the walks and terraces. That these most important adjuncts to architecture are often overlooked or entirely ignored cannot be disputed and yet their importance can hardly be overestimated. It would perhaps not be too much to say that many dwellings, beautiful in themselves, are so marred and disfigured by their surroundings that their intrinsic architectural worth is almost wholly unknown, while many another house, commonplace and inartistic in design, is so beautified by the accessories of landscape as to attract and delight the eye of all beholders.

Especially in outlying or rural districts has the architect opportunities to obtain pleasing effects impossible in the case of city dwellings. Here not only does the unlimited ground area admit of landscape architecture in perfection, but the natural and topographical characteristics of the site, will, in the hands of a skillful and judicious artist, furnish the key note of the design for the dwelling, and form the basis of a combination, beautiful and satisfying because of the perfect concord of all its parts. If the location is rugged and precipitous and the horizon sharply broken by the peaks of tall pines or rocky crags, every sense of fitness and harmony would be violated by a design in which the prevailing lines were long and level and all features of the building uniform and symmetrical.

We would look rather for an irregular treatment high roofs and pinnacles—a broken angular skyline, and a general air of rough vigor and strength. On the other hand should the site be on the sea shore, low and flat with level sand beach and horizon unbroken either towards land or water, then a long, straight roof line, broad verandahs and a general horizontality of style and restfulness of feeling would seem to be compatible with the surroundings. On the materials with which buildings are constructed and the colors of those materials much also will depend if a pleasing, artistic and harmonious effect would be produced.

In the case of the dwelling with weird and rugged environment rough stone or brick of quiet hues for the walls and a dull dark roof would seem most suitable; while for the house on the sea shore or among green fields and shady gardens, lighter and more cheerful materials might be used, with brighter and more varied coloring.

Nor is the principle here laid down to be applied only to rural work. If we examine any architecture recognized as of superior merit, either in this or older lands, we will find the treatment adopted wholly due to natural surroundings and climatic influence; and this is doubtless the chief secret of architectural success. The methods of building were not based on mere whim or fancy, but were the direct result of the practical principles of utility and common sense controlled by a highly cultivated taste for the beautiful.

Take for example the countries of Holland and Belgium or the northern parts of France. Here a picturesque and strongly marked sky line is a striking characteristic of their buildings, a characteristic which may be clearly traced to the natural forces just alluded to. The admiration generally bestowed on these buildings, not to speak of their reproduction in many other lands, bears testimony to their excellence.

As another notable illustration of the same principle, take the architecture of southern Europe, universally conceded to rank amongst the finest architectural achievements of man. In this case the prevailing atmospheric conditions are clear air and bright sunshine, conditions admirably suited to accentuate the contrasts of light and shade. With a keen appreciation of these facts the builders of Italy, for instance, employed methods well calculated to obtain excellent results. Projecting balconies and deeply recessed wall openings, fine and delicately moulded or carved ornament, the free use of color, and everything executed in harmonious and suitable materials all combine to produce buildings which have for ages been an unending source of pleasure and delight.

Until these fundamental principles govern the architecture of our own country we cannot hope for similar success. In studying these fine examples of old work with a view to improvement, it is not the combination of external features, perfect as that is, nor yet the exquisite refinement of detail, much as he may learn from it, that should engross the student's attention. Unless the principles underlying the surface are not only discovered but actually put into practise, but little good will be accomplished.

Suppose one of the well-known facades of Venice, with its profusion of delicate ornament, its glowing colors, the projecting features shining with light, the recessed doorways darkened in shadow and the whole reflected in the blue waters of the Grand Canal. Suppose such a facade transported to one of the streets of a northern town. Imagine those balconies decorated with huge icicles, the interstices of carving and ornament filled with snow. Instead of bright light and deep shadow a dull flat appearing front backed by a duller sky, and we have about as incongruous a picture as the mind could conjure up.

This may be an exaggerated case, but is not a similar mistake, only in lesser degree, too commonly made, with the result that the whole tone of our architecture is correspondingly lowered.

Among the chief characteristics of any town are the disposition and contour of the streets, the sky line formed by the roofs of the buildings, the chimneys, gables and lines of cornices. The architect who has the knowledge and skill to take advantage of broken or uneven sites, to bring the various features of his design into harmony or pleasing contrast with the adjoining buildings or the landscape is to be congratulated. Were this taste and skill more frequently displayed there would be far less of that painful incongruity and discord with which the usual unpicturesque and prosaic conglomeration of roofs and stacks and gables offends, often unknowingly, the eye.

In this connection it will not be out of place to refer to a very common fault in street architecture, that is the treatment of flankages. How many instances can we recall when the flank wall of some dwelling rears its ungraceful sky line obtrusively above the roofs of adjoining houses. Apparently all the resources of its architect were exhausted on the front, leaving not a single idea to expend upon the flank, which stands, grim and bare, a lasting disfigurement and reproach.

Such treatment as this is an infringement of the unwritten law of decency and good taste. Surely something might have been done to make the plain wall tolerable to the eye, even by merely carrying the lines of cornice or mouldings along the sides by means of stone bands or brick sailing courses, to say nothing of some simple design in panel or arcade, either flush or slightly sunk; and just here the writer would like to express his appreciation of a very simple, inexpensive, and to his mind pleasing and effective example in the case of a prominent store building in our own city, whose immense and towering flank has been thus treated.

Another general impression made on the mind of the observer of our domestic architecture is that of its variety. In some of the finest cities in Europe, notably Paris, fault has been found with the monotonous effect produced by the similarity in design of its buildings. With some few exceptions, that is not a prevailing condition on this side the Atlantic. A close study of nature reveals the marvellous beauties of variety, and in following her example we are not likely to err. While, however, nature gives

*Read before the Architectural Guild of Toronto, on Jan. 7th, 1896.

countless examples of both variety and contrast she never violates the laws of harmony; and this is where our mistakes are most "en evidence."

The eclectic tendency of our designers, added to the whims and caprices of a builder, result in the most striking discords. Buildings of diametrically opposite style are placed side by side. The color in which one house may be decorated completely kills both itself and the unfortunate neighbors. This lamentable result would not be nearly so common were the buildings separated from each other by even a narrow stretch of landscape or shrubbery; but the insane desire to crowd the greatest number of houses on the smallest possible area of ground greatly magnifies the evil.

The distinction between variety and difference is a wide one, and it is quite possible to secure the greatest variety as well as the most marked contrasts, without those harsh and discordant effects so frequently seen, did those who are responsible for the design bring judgment and taste and study to bear on the problem?

Let us now very briefly consider domestic architecture in its individual or specific aspect, that is the study of a dwelling in itself. We will, I think, find this aspect to be fully as interesting as the broader or more general one we have been discussing. Under this heading much indeed might be said. We might with interest and no little profit sketch the various stages through which the habitations of man have progressed from the earliest examples down to our own day. We might discuss the suitability and adaptability of the different styles of architecture for domestic buildings. But the barest outline of these facts or theories would extend a paper, such as this, beyond all reasonable limits. We will confine our observations on this occasion to a brief consideration of how the main uses for which a dwelling is erected may be architecturally expressed. In other words, attempt to analyse the principles on which house building, from an æsthetic point of view, is based.

Among the numerous uses of a dwelling house shelter, rest and comfort probably come first. Family privacy and hospitality are likewise important considerations. In design the ideal dwelling should fully and unmistakeably express these facts and sentiments, not to speak of such others as the specific habits or tastes of its occupants may call for. This great variety of sentiment, in the full expression of which domestic architecture has its highest possibilities, furnishes an opportunity for artistic treatment of almost unlimited scope.

But while the sentiments just alluded to are primarily in the interest of the occupier of the house, the commonest ties of humanity demand that a selfish thought of his own interests should not be the only motives which actuate the house builder. He should be as considerate of his neighbors as he would like them to be of him; and even the general public should by no means be forgotten.

Nor does public spiritedness and friendly consideration for others, even in the matter of house building, go without its due reward. The man who thus thinks of others than himself will have, not only the inward satisfaction that such actions invariably bring; he will set an example that others will follow, to the general improvement and thus ultimate benefit of the whole locality, to say nothing of the greatly improved chances of selling property that has been thus brought favorably to the public notice.

Let us now enquire how the sentiments expressive of home life are to be proclaimed, not in words, but in the more enduring materials of construction. To take the one we have first mentioned, viz.: shelter. How this can be most clearly expressed will depend largely on the climatic conditions obtaining in the specific case. If protection from the burning rays of the sun, or the downpouring of heavy rains is the chief consideration, broad verandahs and roofs with spreading eaves would naturally be appropriate. Is resistance to the violence of the wind and storm most necessary, then projections of less extent and the use of stone or brick and other materials suggestive of strength and durability might be used to advantage.

To continue in order, the next sentiment is Rest. One might well ask, how many of our homes suggest this primal sentiment in their external appearance? Precious few, and yet what architectural expression can be more appropriately given to the dwelling place of man? Why is this? Doubtless because it is most difficult of attainment. One need scarcely say that many of our grandest, most expensive and most elaborately built houses are complete failures in this respect.

Here artistic ability and cultivated taste may well expend their best efforts. It is useless to lay down rules in such a case, but a suggestion or two may be offered which will perhaps form a base on which to work.

Rest or repose in buildings may be obtained in a variety of ways. Simplicity and breadth of treatment are of the first importance. By skilful composition the various parts of even a complex structure may be so arranged and grouped as to produce a complete whole, the general purpose of which is easily and quickly though perhaps unknowingly comprehended by mind and eye. It is impossible to give an air of quiet restfulness to a house whose facades are full of features—bays and turrets and balconies, windows large and small, square and round distract the eye and weary the brain in a hopeless search for something on which to rest.

A certain proportion of plain wall surface is an indispensable condition; without it repose is unattainable. A judicious use of materials bearing in mind their colors, will also be most helpful in imparting the expression of rest to a building; those that convey the impression of stability and equipoise, the more sombre colors below, the lighter and brighter above.

Comfort, the next quality to be considered, should also be clearly expressed. Here, good workmanship is of paramount importance. Nothing could be more destructive to a sense of comfort than flimsy or cheap materials put together in a careless or slovenly manner. Windows should be of proper size, convenient shape and in suitable positions. An air of spaciousness or at all events an avoidance of anything approaching a cramped appearance. Ample bays and verandahs will add much to the air of comfort.

Privacy—this most important point is too often neglected. The house is for the use of the family, not for the public or even the near neighbors. If circumstances will allow it, the building should be kept well back from street line, and in any case the exercise of judgment and thoughtfulness in arranging the levels and positions of windows will do much to secure this most desirable property.

There are many other sentiments which might most appropriately be expressed in the exterior design of a house, but time forbids reference to more than the remaining one of those before mentioned, Hospitality. This quality is also not to be overlooked or a most serious defect will be apparent.

It is quite frequently the case that on approaching a house the entrance is the last feature to catch the eye, a feature which, perhaps more than any other, impresses an important character on the building to which it belongs. It is the entrance which stamps on any house an air either of hospitality or exclusiveness. A cramped insignificant door or one not easily seen from the street as certainly conveys the latter impression, as a wide, inviting and prominent entrance augurs a hospitable reception to the approaching guest. The doorway should not only be plainly visible to the passer-by, but a due regard for comfort and shelter in the shape of a projecting portico or recessed entrance of generous dimensions will not fail to add greatly to the attractiveness of any home.

These phonetic qualities of architecture may be as clearly impressed on the humble cottage as on the lordly manor. Because every man's house is his castle is no reason why every modest home should ape the pretentiousness of a palace. We have too many instances of this. It is, perhaps, one of the most frequent and offensive infractions of the laws of good taste. If instead of striving after conspicuousness, the chief aim of our architects was quiet dignity and simplicity, with a due regard for the environments of the home, doubtless we should soon see a very marked improvement in the general and specific character of our domestic architecture.

Thomas A. Edison, the electrician, has been investigating the Pierce & Norris method of making bricks out of sand, plants for which are in operation at London, Dunnville, Port Huron, Sarnia and elsewhere in Ontario. Mr. Edison proposes establishing a plant at his home in New Jersey.

Mr. W. A. B. Fishleigh, of Indian Head, N.W.T., has invented a new heater, a patent for which is now being applied for. The cold air enters from the bottom, and passes up and down through several tubes in the inside of the stove before it is emitted. It is claimed to effect a large saving in fuel.

The Stonecutters' Union of Ottawa have decided to enter into competition with masons in laying stone. This has been brought about by the refusal of the Stonemasons' and Bricklayers' Unions to assist the stonecutters in shutting out stone dressed in Hull, by declining to work on buildings on which it is used.

CONCRETE AS A FIRE-PROOF MATERIAL.

To the Editor of the CANADIAN ARCHITECT AND BUILDER.

SIR,—I venture to submit the following quotations from a paper read by John J. Webster, M. Inst. C. E., before the Institute of Civil Engineers, London, Eng. (Paper No. 2518, Vol. C V, page 256, et. seq):

"d Concrete. Many of the fireproof floors are now constructed of concrete of various materials, either in the form of arches or with flat ceilings built in situ or in slabs; the details of the various systems will be fully described in section 2. Although a certain material may withstand the action of fire satisfactorily, it is important to know what will be the effect upon it of water when in a heated state, for in a conflagration these two elements have to be contended with; and very often water causes the more disastrous effects. It may be mentioned that at the great fire at Lynn on Nov. 26, 1889, when buildings covering an area of 40 acres were destroyed, the water used would have flooded the whole space to a depth of over 7 feet, and at the great fire at Boston on Nov. 28th, 1889, sufficient water was poured upon the structures to cover the site to a depth of 12 feet 7 inches.

"To enable some idea to be formed of the action of fire and water upon various concretes, the author made a series of experiments on test briquettes of various mixture, as follows:

10	briquettes of neat cement				
10	"	1 part cement	1	part sand	
10	"	1 "	"	3	" "
10	"	1 "	"	5	" "
10	"	1 "	"	4	parts ironworks slag
10	"	1 "	"	4	" broken firebrick
10	"	1 "	"	4	" pumice-stone
10	"	1 "	"	4	" coke-breeze
10	"	1 " (plaster of Paris),		4	parts pumice-stone
10	"	1 "	"	4	" broken fire brick
10	"	1 "	"	2	" " " "
10	"	1 "	"	2	" ironworks slag

"The briquettes were of the form usually adopted for testing cement, and the tests were made in a Bailey cement testing machine in the laboratory of University College, Liverpool, Prof. H. S. Hele Shaw, M. Inst. C. E., having kindly placed the use of the machine at the author's disposal. NOTE.—As the stresses to which the various concretes are submitted in an actual structure are very similar to those met with in ordinary engineering works where cement is used, the author felt justified in only applying such a tensile test as is usually adopted in the case of cement.

"Five briquettes of each set were tested at a normal temperature of about 60° Fahrenheit; the other five were carefully heated on the top of a specially built up fire of coal and coke until they were of a light red heat, the average time of exposure to the heat being about five minutes; they were then removed, and whilst hot were quenched with water. A large number of the briquettes lost all cohesive power after being quenched, and it was with difficulty that they were removed intact. As they could not in this state withstand any tensile strain, they were allowed to dry. After three days' exposure to the atmosphere of a warm room they partly regained cohesion, and were then tested. The details of the tests are given in the appendix table I-XII, and the following is a summary of the results: NOTE.—The briquettes were set in air, and were tested within four or five weeks after being moulded.

"None of the above proportions are those adopted by the maker of any particular flooring, but they are such as to yield a good concrete under ordinary conditions, and are sufficient to enable an opinion to be formed of the strength of certain materials in combination, and of their value in fireproof construction."

The whole paper will well repay careful perusal, but your space will not afford a longer extract. The subject is one of great importance in all cities, and is deserving of careful study. When we build "fire-proof" let us seek to use sure material, and thus not bring discredit on "fire-proofing." It would seem to be high time that, in the larger cities at least, fire-proof buildings be insisted on by the authorities.

Yours very truly,

M. J. BUTLER,
M. Inst. C. E.

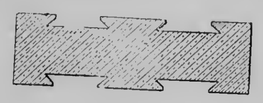
Deseronto, March 9th, 1896.

SUMMARY OF TESTS OF CONCRETE BRIQUETTE.

Number of Table in Appendix	Nature and proportions of materials used in concrete briquettes	Average weight per cubic foot	Breaking weight per square inch at temperature 60° Fahren.	Breaking weight per square inch after being heated and quenched	Average loss per cent of original strength after heating and quenching
		lbs.	lbs.	lbs.	per cent.
I	Neat Portland cement	124.6	554.6	117.2	60.8
II	1 part cement, 1 part sand	120.9	148.9	93.0	80.0
III	1 " " 3 parts "	111.2	109.8	16.7	84.4
IV	1 " " 5 " "	109.7	74.6	15.9	79.8
V	1 part " 4 " iron furnace slag	163.08	108.1	23.06	69.3
VI	1 part cement, 4 parts broken fire brick	95.04	84.4	30.5	50.9
VII	1 part cement, 4 parts Pumice-stone	64.8	94.58	38.3	59.5
III	1 part cement, 4 parts coke breeze	71.65	69.9	39.06	57.1
IX	1 part plaster of Paris, 4 parts broken fire brick	89.6	66.8	16.3	75.0
X	1 part plaster of Paris, 4 parts pumice stone	55.6	57.4	3.4	94.7
XI	1 part of plaster of Paris, 2 parts furnace slag	148.0	223.3	6.9	96.8
XII	1 part plaster of Paris, 2 parts broken fire brick	106.9	167.5	15.7	90.0

RECENT CANADIAN PATENTS.

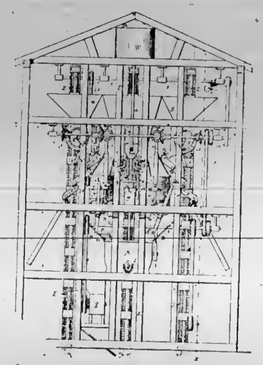
PATENTS have recently been granted in Canada for the following apparatus:—



BRICK.

Patentee: S. I. Adams, Raunhurst, Eng., patented 8th November, 1895; 6 years.

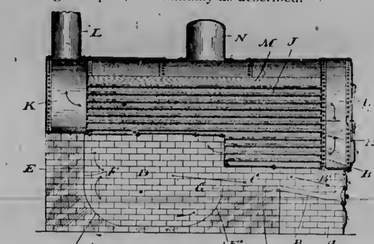
Claim.—A brick, either header, stretcher, quoin, or any kind of brick, provided with dove-tailed shaped recesses either above only or above and below, lengthwise or crosswise, substantially as and for the purposes set forth and as illustrated in the accompanying drawing.



APPARATUS FOR MAKING MORTAR.

Patentee: Thos. D. McClary, Washington, U. S., patented 15th November, 1895; 6 years.

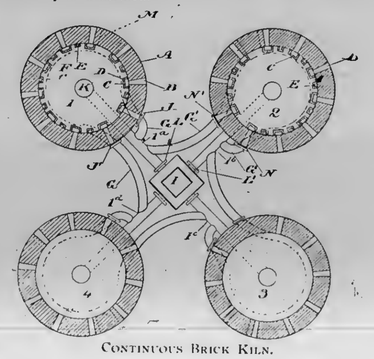
Claim.—In a mortar-making apparatus, the combination of a lime slaker and a rotating lime meter, the latter provided with compartments, each compartment having a false bottom adapted to be adjusted, or removed, the meter arranged above the slaker so as to discharge therein, by gravity. The combination of a lime crusher, a lime meter having compartments provided with false bottoms adapted to be adjusted or removed, as desired, a lime slaker, a water meter having a graduated standard and a float-valve adjustably connected therewith, the said meters arranged to discharge into the slaker, by gravity, the bottom of the slaker provided with ports and screens, a mixing-tank arranged below the slaker, a sand-meter provided with mangle-gear and operating lever and pawl, a feed regulator, and screens arranged between the said meter and mixer, the mixer provided with a discharge port and an interior swinging gate for opening and closing said port, substantially as described.



FURNACE.

Patentee: J. W. F. Sole, Guelph, Ont., patented 11th November, 1895; 6 years.

Claim.—In the combination of a combustion chamber closed at its rear end, against which the heated and liberated gases from the fire chamber may be projected as to be deflected, and a boiler provided with a series of short tubes so located as to be immediately over the fire bridge wall and the fire chamber, and forming outlets through which the inflamed and deflected gases pass to the chamber in the front of the boiler, then through the long tube to the rear chambers and smoke stack. In a device, the combination of the ash chamber A, the grate B, the inlet C, between the fire bridge wall C¹, and the boiler H, the combustion chamber D, having its rear wall E built up to the boiler so as to close the rear end, short tubes H¹ formed in the lower part of the boiler H, front chamber I, long tubes J, rear chamber K, and smoke stack L, substantially as described.



CONTINUOUS BRICK KILN.

Patentee: C. J. Lewis, Grimsby, Ont., patented 22nd November, 1895; 6 years.

Claim.—A brick kiln consisting of an outer wall, a series of vertical fire chambers on the inner side of the outer wall, the upper end of each of the vertical fire chambers opening into the body of the kiln, a series of vertical hot air flues arranged around the inner sides of the outer wall and extending through the floor of the kiln, a flue connecting together the lower ends of each of the hot air flues, a main flue to the chimney into which the connecting flue discharges, a draft well formed centrally through the floor of the kiln into the main flue, and dampers for the main flue and connecting flue, substantially as specified.

Composition for artificial stone, Frederick Brown and John King, both of Fort William, Ont.

Radiator for steam heating, F. E. Backus, Williamsport, U. S.

Pipe trap, H. F. Pool, Lynn, Mass.

Josiah Fairbank, Helena, Ohio, machine for erecting frame structures.

Oliver Schlemmer, Cincinnati, Ohio; hot water heating apparatus.

J. J. Baskerville, Duluth, Minn., school desk and seat.

John S. Burton, Danville, Ill., gable ornament for buildings.

Robert W. King, Toronto, Ont., ventilating apparatus.

J. R. Bate, Cincinnati, Ohio, process of preserving wood fibre.

MONTREAL.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

IT is a well-known fact in Montreal that a certain class of architects undertake to carry out work much below the customary percentage of 5% on the cost of the building. The practice generally indulged in is to undertake the preparation of plans and specifications, taking in tenders and superintendence at a cost of 2½% to the proprietor, who is left under the impression that he is saving 2½%, and congratulates himself at not having fallen in with some of those high priced architects with their exhorbitant charges of 5%. The bogus architect, as we may be allowed to call him, takes the responsibility of taking out quantities when tenders are about to be called for, and charges a certain fee to each contractor tendering on the job, for a copy of his bill of quantities. Moreover the successful tenderer, under the pretext of renumerating the architect for the work and responsibility incurred by the taking out of these quantities, is forced to pay him an additional fee of 2½% on the acceptance of his tender on the full amount of same. Thus it will be seen the proprietor pays indirectly to the architect more than the customary commission of 5%, as it is evident the contractor reimburses himself for the 2½% commission he has paid, and, moreover, the architect loses his independence towards the contractor, and is entirely at his mercy. As a result, very often, the latter is the sole judge of the interpretation of the plans and specifications, and if he finds he has not made a sufficient allowance for profit or contingencies in his original tender, he invariably tries to save every penny he can on the material and workmanship employed in the building. Honest contractors should unite together and refrain in a body from tendering in the office of an architect who will indulge in these practices, as not only will they have the disadvantage of invariably meeting with the recriminations of the proprietor but also risk their business reputation and lower their class of work below the standard, with the result of being refused the patronage and encouragement of honest architects.

Another well-known method of "boodling" is in the inducement of manufacturers to architects to specify their goods. Manufacturers, anxious to introduce a new heating furnace or other goods or materials used in buildings, pay a certain percentage to architects on the amount of goods specified, for their influence in helping them to introduce the same. All these dishonest practices should be brought to light and strongly condemned, so that persons intending to build may guard themselves against persons carrying on business in a suspicious manner, and encourage the honest, straightforward and deserving class of architects and contractors, with mutual advantages to all concerned.

AUGE BILL.

The Auge Bill has undergone considerable modifications at the last session of the Legislature (21st December, 1895). It has been first modified so that the workingmen's privilege will apply to the plus value only created by their work, and not on the original value, and the starting point of the delay of 30 days allowed for the registration of privileges has been fixed at when the building is ready for occupancy. Architects have not been given a privilege which they did not enjoy before. Their privilege comes next to that of the workman and before that of the contractor. The order of privileges is as follows: 1st, the laborer; 2nd, the workmen; 3rd, the architect; 4th, the contractor. The obscure clause about the sub-contractor, which I explained and condemned in my correspondence on the Auge Bill in the August number of the CANADIAN ARCHITECT AND BUILDER has been cancelled. The privilege given the finisher of materials takes rank only after the privileges previously registered; and when the proprietor has paid the contractor and received notice from the furnisher of materials of money due him by the contractor, the proprietor cannot be held responsible for the same. This amendment is a very desirable one. When a proprietor builds himself, without the intermediary aid of a contractor, the notices from the privileged parties should be addressed to the persons who furnish the funds for the erection of the building. "Le Prix Courant" in an editorial expresses the opinion that as a whole the Auge law is more reasonable and practicable than previously, but that it would have been more simple and preferable to abolish the same altogether.

CONTRACTORS' DRIVE.

After a lapse of seven years the contractors of this city have revived their popular drives, the first of which was held on Saturday, the 29th of February. Messrs. Peter Wand and W. A. Stephenson assumed the management, and upwards of sixty well-known contractors enjoyed the outing. Their destination was Peloquin's hotel, Sault au Recollet, where an excellent dinner was served, the chair being occupied by Mr. Wand, and the vice-chair by Mr. Peter Lyall. After numerous toasts and speeches, the company returned about ten o'clock and congratulated themselves upon the re-union.

CORRECTION.

IN the reference in our New Year Number to the new Wesley College building, Winnipeg, should have been stated that Messrs. George Browne and S. Frank Peters were associate architects of the building.

T. M. Hennessy, architectural draughtsman of the Department of Public Works, has compiled a most accurate and useful table, setting forth the comparative sizes, absorbing properties, specific gravity, etc., of the different pressed brick manufactured in the Province of Ontario.

BUILDING STONES OF EASTERN ONTARIO.*

By Andrew Bell.

NOTES ON THE BUILDING STONES FOUND IN EASTERN ONTARIO AND LOWER OTTAWA VALLEY, EMBRACING THAT PART OF THE PROVINCE AND OTTAWA VALLEY EAST OF A LINE FROM THE HEAD OF THE BAY OF QUINTE TO MATTAWA ON THE OTTAWA.

The following notes are compiled from personal observations, extending over the past 40 years, during which time I was in active practice in that region, both in engineering and architectural building, but principally the former.

The region contains a great variety of valuable, useful and ornamental building stones, in unlimited quantities, for almost any purpose in building, except for highly ornamental cutting such as can be done with the Ohio and similar free stones—of that there may be said to be none or next to none. When I mention a stone that will cut well, I mean the good ordinary cutting for general building, as distinguished from a stone that can be easily cut for ornamental purposes, as before mentioned.

The subject, to do it justice, would require a large volume instead of a short paper; the following notes, on that account, may appear to be rather fragmentary.

I do not speak of the different building stones from a scientific, but from a practical point of view, as I saw them.

Geology divides the rocks in this territory into two general groups—the primitive or igneous formations, and the sedimentary rocks, comprising the Lower Silurian groups. The first covers perhaps two-thirds of the district, and, for our purpose, may be divided into "Granite Proper" and the "Laurentian." The other comprises the "Potsdam Sandstone," the "Trenton and Black River" groups of limestone, (which I will for the sake of brevity call the "Trenton group") and the "Utica Slate," which latter, however, does not furnish any good building stone worth mentioning.

I will take them in the above order.

GRANITE PROPER.

This is not found exposed in many places, or covering a large area. The best I know of, and the most accessible, is in the vicinity and north of Gananoque, especially at Charleston Lake. There it can be obtained, free from flaws, in any desired size. It is, of course, as all granites are, hard to quarry and hard to cut, but breaks out well with the plug and feather, and, although hard, cuts well and takes a fine polish. It varies in color from light grey to a beautiful mottled red, closely resembling and fully equal to the celebrated Peterhead granite. It looks its best when polished, as in pillars, &c., but would also be admirable for basements.

Granite is found also at several places in the counties of Lanark, Renfrew, Addington, and on the Ottawa, but I do not remember any of them in those localities that are at present easily accessible. Some granite has been quarried near Gananoque, but to such a limited extent, and not at all in the best localities in which it is found, that it may be considered as yet unknown to the general public.

LAURENTIAN.

Wherever this prevails it generally furnishes fairly good stone for rough rubble work. In many places gneiss is found in courses from 6 to 10 inches thick, with good natural beds, not requiring much dressing, varying from nearly white to dark grey, but can hardly be considered a desirable stone to take to any distance, although useful in its immediate locality.

But the strong point in the Laurentian is its crystalline limestones, marbles, serpentines and dolomite. They are found all over where the Laurentian prevails in great variety—generally coarsely crystallized, although often fine grained. In color generally pure white, light and dark grey, white and grey mixed, or beautifully streaked and mottled with grey and white, or light and dark grey. It is sometimes nearly black, often green, mottled green and white, and sometimes pink, salmon-colored and yellow, and various other colors and mixtures. Generally the crystalline limestones are more in masses than in beds, although sometimes found in well-defined courses from 6 to 24 inches thick, with good natural beds. Stones of almost any desired size can be taken out. They are fairly easily quarried—much easier than granite—break well with plug and feather, cut well, almost always take a fine polish, even when very coarsely crystallized, and are generally very durable. At Portage du Fort and many other places along the Ottawa they are found pure white, or nearly so. In the townships of Dalhousie, Lanark, Pakenham, but especially at and near Arnprior, where is obtained the well-known "Arnprior marble," they are light grey, grey and white, or light and dark grey mixed, with the markings often very beautiful. These, although giving splendid dimension stone and ashlar, are rather too sombre in hue to be ever much in demand for ornamental purposes. They would be good in basements, or sawn into pavements, &c.

In the mountain, only a few hundred yards from the Calumet station on the C. P. Railway, there is a large mass of green mottled serpentine, which could be taken out in pieces of any required size. It is not very coarse-grained, can be comparatively easily quarried, cut or sawn, and shows a beautiful green mottled surface when polished. Some 50 years ago a quarry of this was opened and a small mill built on the Calumet River close to the quarry to saw it, but I do not know if any was ever sawn and put on the market. Since then it seems to have been forgotten. It should make good pavement for halls, green-houses, &c., and might be used to advantage for many other ornamental purposes.

At Massonog Lake, in the township of Barrie, some 15 or 20 miles north of Kaladar Station, on the Toronto branch of the C. P. R., there is a mountain of marble, mostly white, rising almost perpendicularly out of the lake to a height of 300 feet. It is fine in grain, resembling in appearance the well-known Italian and Vermont marbles, but all the specimens I have examined contained small particles of quartz, which is a serious drawback to its cutting or polishing. It is situated in a wild, almost uninhabited part of the country, and it is therefore probable that it has not yet been carefully examined, nor any regular quarries opened. If that were done intelligently, no doubt some valuable beds of marble would be found in it. As before mentioned, it is mostly white, but some parts or beds are a beautiful light pink, and some spotted and mottled with black, grey, red and other colors.

Near Renfrew a rather fine-grained kind is found, which is white, prettily spotted with light gray or blue, and sometimes with red. Near Bridgewater it is found black and white, or what might be called "pepper and salt."

The white coarsely crystallized marbles when polished, and they take a very fine polish, are often very beautiful on account of the irridescent effect of the large crystals. In Huntley, Darling and several other places there are found small masses of these marbles—light pink, salmon-colored and yellow. They are generally as yet unexplored.

All the crystalline limestones would give good paving for halls of public buildings, &c., and could be used for the thousand and one other purposes which will suggest themselves to the architect. The quantity is unlimited and the variety endless.

POTSDAM SANDSTONE.

This produces generally a hard and often coarse-grained sandstone—sometimes pure white, but oftener yellowish white, or yellow—often red, or streaked with red and yellowish white, or two or three shades of red, and sometimes white or yellowish white beautifully mottled and streaked with dark purple. It often contains a good deal of iron, which, when exposed, oxidizes and gives an appearance of age to the building, not at all unpleasing to the eye.

Some beds in many places, such as near Pembroke, in Ramsay, near Pembroke; in Ramsay, near Almonte; at Lombardy, near Smith's Falls; in North Elmsley, near Perth, and several places along the Rideau Canal, it gives really good dimension stone of the various colors mentioned, and can be got in courses from 12 to 24 inches thick, with good natural beds, requiring little dressing to lay close joints. The thicker beds often cut fairly well, and sometimes would almost merit the term of free stone.

At Dog Lake, on the Rideau Canal, I have seen it in thick courses of a pleasing light red color. This would make good dimension stone, or good rubble, as it splits parallel with the natural beds. It is coarse in grain but cuts well.

In Ramsay at Lombardy and at Pembroke some beds are white or yellowish white, a good example of which may be seen in the Court House at Pembroke, and several buildings at Smith's Falls.

The Potsdam produces splendid rubble stone in a great variety of colors, almost always pleasing—quarries easily, generally with good, natural beds, and, although hard, can be easily shaped for use with the hammer or point.

At or near Hudson, on the Ottawa, it is found of a reddish color, a good example of which is the new Catholic church at Oka, opposite Hudson. At Pembroke, besides white, it is found red, or striped red and white, or with two or three shades of red, a good example of which is the new Government buildings at Pembroke. In Beckwith, some six miles from Carleton Place, and 2½ miles from the railway, and also in the township of Montague, it is in beds from 4 to 10 inches thick, nearly white, can be quarried easily, has true natural beds, and can be laid up as easily as brick, without any further preparation than breaking to sizes required. In other places, such as Huntley, Ramsay, &c., I have seen it with a white or bluish glassy appearance, often translucent but very hard.

In North Elmsley, near Perth and near the Rideau Canal, there are large quantities white, yellowish white or bright yellow, and the same colors, beautifully striped and mottled with dark purple. It is easily quarried and requires little dressing for use as coursed or broken coursed rubble. Good examples of it can be seen in the railway station at Perth and in the new Government buildings at Almonte, Carleton Place and Smith's Falls. These Government buildings are trimmed with Nova Scotia red sandstone, which matches the rubble very well. It looks well also trimmed with Credit Valley stone and with Ohio free stone. Near Ottawa it is abundant in good form for rubble, as may be seen in the Parliament buildings at Ottawa, which, as trimmed with Ohio free stone, show to great advantage the beauty of this class of rubble stone.

THE TRENTON GROUP—LIMESTONE.

This covers a large area and produces our best stone for heavy work, such as canal locks, railway bridges, &c. It is generally a nearly pure carbonate of lime, sometimes mixed with carbonate of magnesia, and often carries a large proportion of sand. I, in common with many of the engineers in Eastern Ontario and Montreal, divide it into two classes, called for want of better names, "Grey" and "Blue," although the color designation is somewhat misleading.

For dimension stone, the "Grey" is found in even beds from one to three feet thick. It is easily quarried, breaks out well with plug and feather, cuts easily and well and is very durable. The grey has a coarse or open grain, and shows a torn or ragged fracture when broken. It produces excellent dimension stone for building. It is abundant and good at Terrebonne, back of Montreal, at Caughnawaga, at East Hawesbury, at Cumberland, at Gloucester, at Hull and at many other places. Examples of its adaptation to the better class of building may be seen in the Court House, the Quebec Bank and other buildings at Ottawa, and in several buildings at Hull. It also gives good rubble, easily dressed into what is locally known as "shoddy."

The "Blue" is fine and close in grain, breaks with a sharp clear cut and often conceidal fracture, presenting a glassy surface. It does not cut nearly so well as the grey, often eating out before the tool, leaving concave hollows. It is not so durable as the grey, nor does it give as good results for dimension stone. It produces abundance of rubble; in fact it is the most commonly used stone all over the country where it can be got, as it is comparatively soft, easily quarried, and requires little preparation for use. The "Blue" is generally bright in appearance when first quarried, but unfortunately fades in a few years and becomes a "sickly" white, as may be seen at Kingston and other places. It makes a poor contrast trimmed with Ohio free stone, but looks much better with the yellow sandstone of the Potsdam formation.

Near Cornwall, near Pakenham and some other places there are thick beds, fine-grained, which take a fine polish, and are first black, with a few white spots when polished. These can be easily sawn, polished and used for paving, and also for any other purpose where it is desirable to use a black marble. They are locally called "Black Marble."

In the township of Beckwith, close to Carleton Place and the C. P. Railway, there is a large quantity, which, as far as I know, is unique. It is of the grey variety, as far as texture is concerned, and is in masses, not having very clearly defined beds, but is easily quarried to any desired size, tools and bush hammers very well, and is really a valuable building stone, although unfortunately the color—a dark grey brown, gloomy in appearance—is much against it. However, it does well in basements, making a ground work from which to start a brighter superstructure. It is now being quarried extensively, and is used in all the towns and villages for a considerable distance in every direction, for sills, lintels, corners, plinths, &c., for which it seems to be well adapted. It is known as "Beckwith Stone" and is a nearly pure carbonate of lime and magnesia, carrying only 3% of silica or other impurities indissolvable in hydrochloric acid. Strange to say, it is often erroneously called free stone or sand stone. A somewhat similar stone is found in Maitland, but it is not so dark in color, and is not nearly so good.

All the region I have spoken of is rich in valuable building stones, of very varied colors and qualities much more so than the western part of the province, and could be drawn on to advantage for buildings in the rapidly growing city of Toronto—the only objection being that they are generally somewhat harder than the Toronto builders have been accustomed to.

I have spoken only of what I have seen myself. As a large portion of the district is as yet comparatively unexplored, or little known, no doubt what I have enumerated does not nearly cover the whole field.

In concluding I will take the liberty of recapitulating the building stones heretofore spoken of, which could be advantageously brought to and used in Toronto:

Granite—Especially that from Charleston Lake and in rear of Gananoque and Kingston.

The various Crystalline Limestones or Marbles of the Laurentian formation.

Dimension Stone and Rubble, especially the latter from the Potsdam sandstone. The rubble could be used, either coursed, broken coursed or random, in churches, detached private residences, &c., either trimmed with Potsdam, or with Credit Valley, or Ohio stone.

From the Trenton group, black limestone or "black marble," and the "Beckwith stone."

All of the above can now be obtained close to railways or navigation, although in many cases the quarries are not being worked at present, but soon would be if there was any demand for the stone.

I will be glad at any time to furnish any further information I can as to where and how any of these building stones can be obtained if wanted.

*Paper read before the Ontario Association of Architects.

CANADIAN SOCIETY OF CIVIL ENGINEERS.

The following is the Code of Engineering Ethics recently adopted by the Canadian Society of Civil Engineers:—

DUTY OF THE ENGINEER TO HIS CLIENT.

1.—Every member of the Society should perform the work he undertakes to do to the best of his ability and in the true spirit of his engagement, feeling it to be his duty to present all ascertained facts in their true light.

THE CLIENT'S OBLIGATION TO THE ADVISER.

2. The Civil Engineer has a right to expect from his client the same consideration and deference to his opinion as is by their clients accorded to the members of other professions—Law and Medicine for example—and without which the adviser should decline to advise. The surest way for the Engineer to obtain such necessary consideration and deference from the public will be found in his manner of carrying himself.

MUTUAL RELATIONS OF CHIEF AND ASSISTANT.

3.—The Assistant Engineer must loyally obey and support his Chief, to whom it will be his duty to report directly on all matters relating to the work or which they may be jointly engaged. His report should be full and explicit on all important points and exact to the best of the Assistant's knowledge and belief, eschewing nothing, even though going to show that previous reports have been inaccurate or not duly weighed in some particulars affecting the well being of the business in hand.

4.—The Assistant Engineer is entitled to look to his Chief for, and to receive from him, advice for his guidance in the proper performance of his duties and, where right, to expect his support in matters in dispute between him (the Assistant) and his subordinates or between him and the contractors working under him. He is also entitled to the aid of the Chief Engineer's professional experience or counsel where unlooked for or extraordinary difficulties present themselves or changes of original plan may be called for in the work on which they are associated, so that responsibility may be fairly apportioned between them.

5. It is the duty of both Chief and Assistant, each in his department, to study proper economy in the doing of the work, the management of which they have undertaken, and in every way consistent with the maintaining of the good character of the work to make the client's interest the guiding object.

6.—The Engineer may legitimately suggest experiments with a view to improvement whether in methods of doing the work which he oversees or for raising its character, but such experiments should only be undertaken with the full consent and cooperation of the party, whether client or contractor, on whom the expense may fall, and on the understanding that to them will accrue all pecuniary benefit from the success of the experiment.

7.—It shall be considered unprofessional for any member of this Society to seek the position of an expert to report on any work that is in charge of a recognized Engineer.

8.—It shall be the duty of any Engineer before examining any work with a view to report thereon to give the Engineer due notice before going on with the investigation, in order that he may have every facility to explain and sustain his methods of carrying on the work in question.

PROFESSIONAL SERVICES OF ENGINEERS TO EACH OTHER.

9.—Interchange of professional assistance between members, as tending to promote fraternal intercourse and mutual good-will is not to be discouraged, but neither is it to be considered obligatory on a member to respond to the request of a fellow-member for professional counsel or assistance. Service so rendered must be entirely voluntary on the part of the member whose aid is sought.

PECUNIARY MATTERS, ADVERTISING, ETC.

10—The Civil Engineer may consistently with professional status take out patents for new inventions or for improvements on old ones, and may sell or otherwise dispose of the patents for his own advantage. He may undertake surveys and the engineering of works by contract, or he may take contracts for the construction of works on a percentage of their cost. Advertising with a view to attracting business should, where resorted to, be as far as possible free from egotistic or self-laudatory references and expressed in language not derogatory to the dignity of the profession.

DUTIES OF THE ENGINEER TO THE PUBLIC.

11.—The Civil Engineer whose advice is sought in respect to the usefulness, practicability and cost of a work should before expressing his opinion obtain reliable information on all points involved in the matter submitted to his judgment, including the probable paying capacity of the contemplated undertaking. He must be cautious how he recommends large preliminary outlay; should avoid connecting himself with schemes or projects of merely speculative character, always bearing in mind that his professional reputation will be to a great extent judged by the inherent merits and commercial value of the undertakings with which his name may come to be associated.

At the ordinary meeting of the Society held at 112 Mansfield St., Montreal, on the 13th February, the President, Mr. Herbert Wallis, presided. The evening was occupied in the discussion of Mr. W. Bell Dawson's paper on "Retaining Walls," in which Messrs. H. Irwin and J. G. Kerry took a prominent part.

At the meeting on Thursday, February 27th, at which Mr. Wallis, the President, also presided, a paper on the Penn Yan (N.Y.) Waterworks by Mr. Angus Smith, student of the Society, was read by the Secretary. There was also a debate on the following resolution: "That engineering works should be constructed by day's work under the immediate direction of an engineer instead of being done through a contractor." The debate was opened by Mr. W. J. Sproule, and was taken part in by Messrs. Wallis, Irwin, Smith, Kerry, and others.

CORRESPONDENCE.

[Letters are invited for this department on subjects relating to the building interests. To secure insertion, all communications must be accompanied by the name and address of the author, not necessarily for publication. The publisher will not assume responsibility for the opinions of correspondents.]

BUILDING RIGHTS AND MEASUREMENTS.

MONTREAL, Jan. 25, 1896.

To the Editor of the CANADIAN ARCHITECT AND BUILDER.

SIR, As there are differences of opinion, would you kindly give the law of the Province of Quebec which governs the following questions concerning walls:

1st. If the foundation of a building requires to be planked or concreted say 6 feet wide, do the respective proprietors pay 3 feet each? If the footings are 4 feet wide when there is no plank or concrete, do they pay 2 feet each, presuming in both cases there is a 2 foot stone wall built on it? And do each pay 3 feet or 2 feet of excavation respectively, or just the thickness of the 2 feet wall?

2nd. How many feet English measure are there in a toise of masonry.

3rd. How many bricks are there in a cubic foot of brick work, and does the different thicknesses of a brick wall make any difference in the number? By answering the above in your next edition you will greatly oblige.

A SUBSCRIBER.

[ANSWER.—According to Act 512 and 513 of the Civil Code of Lower Canada, all those that have right to community of wall are obliged to contribute to repairs and reconstruction to half the amount of value of the whole portion of said wall they use, unless they abandon their claims to community. 2nd. The practice in Montreal is to count 80 cubic feet in English measure per toise; measurements vary, however, according to locality. 3rd. A square foot of brick veneering is assumed to contain 7 bricks, an 8 inch wall 14 bricks, and although at this rate a cubic foot of brickwork should contain 21 bricks, it is generally reckoned as 20, there being a little less than 21 bricks in a cubic foot.—EDITOR C. A. & B.]

FIRE RESISTING STRUCTURES.

To the Editor of the CANADIAN ARCHITECT AND BUILDER.

SIR, Regarding the article which appeared under the above heading in your February issue, I beg to submit a resume of the report of F. D. Moore, President of the Continental Insurance Co., and a member of the Board of Examiners of the Building Department of the City of New York. This gentleman says he has visited and examined the Manhattan building in his official capacity, and clearly states that the cause of the accident was due to the box girder supporting the floors not being protected; it sagged and carried the upper floors along with it. Mr. Moore also calls attention to one part of the building, composed entirely of wood and glass, which burned fiercely.

This gentleman's report is, in my humble opinion, of far more importance than the opinion of chief Bonner, who, as a fireman, sees a building only when it is on fire. For a man like Chief Bonner to pass an opinion on fireproof buildings, of which he knows nothing, is simply ridiculous. Chief Bonner should learn first that iron which is not properly protected, is not considered fireproof by any one who knows what constitutes a fireproof building.

What does chief Bonner now think of his wooden buildings in the light of the Troy and Utica fires? The buildings, destroyed in those fires were, according to your statement, the kind he recommends. I would say further, that New York City should never be taken as an example as regards fireproof construction. I dare say there are thousands of buildings in New York that are called fireproof, but judging from what I have personally seen, I am sure that not one-half of them are actually fireproof. There is no law to prevent anyone from calling a cow shed fireproof if he chooses be may advertise it, post up notices all over that the building is fireproof, and no one may be the wiser until it takes fire; then men like Chief Bonner will say fireproof buildings are a failure.

I see only one remedy for this condition of affairs, and that is for the government to appoint an expert, and make it a criminal offence for anyone to advertise a building as fireproof without a certificate to that effect from the government expert. If that were done you would be surprised to see how few really fireproof buildings there are, and how easily they could be made fireproof, and those who intend to put up a really fireproof building would be protected against unscrupulous competitors with their cheap imitations as well as against fraud and ignorance.

Yours truly,

N. T. GAGNON.

TESTS OF CANADIAN BRICKS.

By the courtesy of Mr. Kivas Tully, chief architect of the Public Works Department of Ontario, we are enabled to publish the accompanying table showing the result of tests of Canadian pressed brick made during the past three years for the Public Works Department under Mr. Tully's direction. The tests were made in the laboratory of the School of Practical Science, Toronto. The table of results is as follows:

FORM IA SHEWING SIZES, TESTS FOR ABSORPTION, ETC., OF PRESSED BRICK MANUFACTURED IN ONTARIO, MADE BY MESSRS. TULLY AND WRIGHT AT SCHOOL OF PRACTICAL SCIENCE, TORONTO.

No.	Label.	Dimensions of Brick—Length, Breadth, Thickness.	Cubic Contents	Weight in ozs. after 4 hours drying.	Weight in ozs. after 4 hrs. in water.	Absorbed ozs.	Weight per cub. inch in ozs.	Specific gravity.
1.	T. Nightingale.....	8.42" x 4.12" x 2.46"	85.38"	88.40 oz	100.28 oz	11.52 oz	1.04	1.76
2.	Boyd.....	8.36" x 4.11" x 2.36"	80.81"	82.25 oz	94.57 oz	12.32 oz	1.02	1.82
3.	R. P. B. Co.....	8.38" x 4.11" x 2.48"	85.02"	90.44 oz	102.42 oz	11.62 oz	1.06	1.87
4.	T. P. B. Co.....	8.39" x 4.11" x 2.40"	82.73"	84.21 oz	97.17 oz	12.37 oz	1.02	1.76

b8.	Garson P. & Co.	8.75" x 4.25" x 2.5"	92.968"	93.32 oz	110.48 oz	17.16 oz	1.09	1.74
c9.	Garson P. & Co.	8.37" x 4.1875" x 2.5025"	86.868"	87	104	17	.98	1.67

NOTE:—As respects the durability and finish of the first six specimens, there is practically no difference; all are good with a slight difference in color.

"Don" (5) and "Ontario" (6) specimens were tested for crushing by Professor Wright 175,000, about 5,100 lbs. per cubic inch.

"Don" (5) shows least absorption; G. P. & Co. (b 8) and (c 9) show greatest absorption.

KIVAS TULLY, Architect.
Department of Public Works, Ontario, January 30th, 1896.

The South Kensington Work on "Building Construction," referring to the absorption test, says, "The amount of water a good brick will absorb is a very good indication of its quality. Insufficiently burnt bricks absorb a larger proportion, and are sure to decay in a short time. It is generally stated in books that a good brick should not absorb more than one-fifteenth of its weight of water. The absorption of average bricks is, however, generally about one-sixth of their weight, and it is only very highly vitrified bricks that absorb so little as one-thirteenth or one-fifteenth."

It is said by those who have made a study of the subject, that a brick may absorb a large percentage of water and yet not disintegrate easily. Disintegration is largely caused by water and frost. The water absorbed by the brick becomes frozen, causing the expansion and decay of the brick. Another cause of disintegration is lime, which under the action of water, burns out, and causes the brick to go to pieces.

It has been noticed that bricks which absorb less than 10 per cent. and upwards of 15 per cent. of water are better able to withstand the action of the water than those which absorb from 10 to 15 per cent. The water absorbed by the former is not enough to cause sufficient expansion to destroy the structure of the material, while the latter are so porous that the water absorbed quickly drains out again without allowing time for the destructive influence of frost to operate upon the brick. It is estimated that a brick which absorbs 20 per cent. of water will drain out the greater part of this water again in from 20 minutes to half an hour, so that unless frost sets in immediately after rain there is little danger of the brick being injured. A brick which absorbs say 12 per cent. of moisture is considered much more dangerous than one which absorbs 20 per cent.

As very little appears to be known with regard to the character and quality of Canadian manufactured bricks, we would be pleased to be furnished with any further information on the subject, and invite our readers who may be able to do so, to contribute data on this line.

ONTARIO ARCHITECTS' ACT.

WE are pleased to observe that the Ontario Architects' Act, embodying the amendments desired by the Ontario Association of Architects, has passed its second reading in the Legislature. The Association have taken pains to explain very clearly the meaning and effect of the proposed amendments, and the legislators with scarcely an exception have had the good sense to see that the measure is one which will operate in the public interest. As it is an unwritten law of legislative bodies that a measure which passes its second reading without serious opposition is entitled to a third reading, we look for the adoption of the measure at an early day.

COMPLIMENTARY OF THE "ARCHITECT AND BUILDER."

WE have recently received a number of kindly worded letters from some of our subscribers, from which we take the liberty to print the following extracts:

"Many thanks for the copy of your New Year's number of the CANADIAN ARCHITECT AND BUILDER. It is a truly admirable production, and a credit to the arts and crafts of the country in every respect." Hamilton McCarthy, R.C.A., Toronto.

"I wish to say how much pleasure it gives me to receive the ARCHITECT AND BUILDER monthly, and how much it must please every subscriber to see its rapid progress. The present number is a piece of art for which the publisher deserves the highest credit."—James Mather, Architect, Ottawa.

"I desire to congratulate you upon the greatly improved appearance of your journal, as evidenced in the recent number, both as regards the illustrations, letter press and advertisements; the latter having sketch illustrations, are made more attractive, and consequently receive more attention at the hands of the profession." Geo. W. Gouinlock, Architect, Toronto.

STUDENTS' DEPARTMENT.

MAXIMS FOR DRAFTSMEN.

THE power of shading rightly depends mainly on lightness of hand and keenness of sight; but there are other qualities required in drawing dependent not only on lightness, but steadiness of hand; and the eye to be perfect in its power, must be made accurate as well as keen, and not only see shrewdly, but measure justly.

Nearly all expression of form, in drawing, depends on your power of graduating delicately; and the graduation is always most skillful which passes from one tint to another very little paler.

In darkness of ground there is the light of the little pebbles or dust; in darkness or foliage, the glitter of the leaves; in the darkness of flesh, transparency; in that of stone, granulation; in every case there is some mingling of light.

An entire master of the pencil or brush ought indeed, to be able to draw any form at once as Giotto his circle; but such skill as this is only to be expected of the consummate master, having pencil in hand all his life, and all day long, hence, the force of Giotto's proof of his skill. Ruskin.

THE STAIRCASE.

STAIRCASES, says the author of the Architectural Association prize essay on "The History and Development of The Staircase," have been conveniently classed under the following six descriptions: (1), the spiral or newel staircase; (2), the straight staircase; (3) that which goes round two, three or four sides of a rectilinear figure; (4), a central ascent with two branches; (5), the circular, semi-circular, or oval-open well staircase; (6), compound, composed of straight flight in conjunction with curves. The first two and the third of these we have already noticed as being the usual forms during the Mediæval and Transitional periods respectively, and we shall frequently find examples of the remaining three among the staircases of the Renaissance. The circular or oval well staircase was really the mediæval spiral staircase in an improved form. The fact of the mediæval newel being solid practically placed a limit on its diameter, but the open newel could be made of any size, and consequently the number of steps in each circuit increased, thus allowing the ascent to be made with a less number of revolutions, and greatly diminishing the inconvenience resulting from the varying width of each tread. Geometrical staircases were not introduced till the latter part of the reign of Charles II., and Sir Christopher Wren is said to have constructed the first in the south-west Tower of St. Paul's Cathedral. Winding staircases were very often used during the Renaissance, especially in its earlier stage.

TORONTO SKETCH CLUB.

A meeting of the Toronto Sketch Club was held at the office of Messrs. Strickland & Symons on Tuesday, Jan. 21st, when Mr. Wickson acted as critic. The subject for competition was the Corner of a Court Yard shewing a Tower, Gable and Entrance—view taken from inside. This was a study in composition and grouping more than detail. The designs were not so numerous as on previous occasions as the subject was rather difficult for the junior members. Mr. E. R. Rolph took first place for the draughtsmen with a design in French Gothic, and Mr. Melville P. White first place for the students.

A meeting was held on Tuesday, Feb. 4th, at Messrs. Curry & Baker's office. Plans were submitted for a farm house for a farm of 100 acres, the owner of the house to work on farm. Mr. Baker criticised the various drawings and considered them all too elaborate for a house of the requirements. The kitchen should be the most important room in the house, whereas the drawing-room in nearly all cases was given the most study. They were more suitable for a gentleman farmer that would have a smaller house attached for farm hands. Mr. C. P. Meredith took first place for the students. The next meeting will be held in Mr. Langton's office on Tuesday, Feb. 18th.

THE SUBURBAN HOUSE.*

By R. J. Edwards.

When I was asked by our esteemed Secretary to contribute a paper for this occasion, I may say it was on the spur of the moment I consented; and I have since found it was more easily promised than accomplished in the short time at my disposal. You will, therefore, I beg, expect but a sketchy treatment of the subject I have chosen. I am not sure but that that is the proper treatment anyway, for a too-ambitious is not, perhaps, the best spirit in which to approach the subject in actual practice.

The kind of house I have in my mind is one that will be within the reach of the comparatively poor man. Though living in the city he has not lost, we will suppose, his love of the ideal sun and air of the country. In building his house he can obtain these for all the living rooms only by having it surrounded by sufficient open ground. Happily, the electric railway makes it possible to build where land is cheap without too great a sacrifice of time in journeying to and from business, and in this city he need not go outside the limits to obtain the advantages of the country, together with those necessities of modern life—water, sewers, gas, and I hope soon we shall be able to add, Sunday cars. The cost of the building may be anywhere from $2,000 up, according to the accommodation required.

I venture to say that architectural taste would gain immensely in this place if all fire limit restrictions were withdrawn, except in the more central districts, provided the houses were kept a reasonable distance apart. Nothing, in my opinion, has had so much influence in making the dwellings of Toronto commonplace as the absurd by-laws the people have imposed on themselves. The effect has been to build whole streets of attached brick or brick-fronted houses. Scores of streets have been architecturally ruined in this way, that might have been attractive had they been built up with detached frame or brick cottages on comparatively wide lots. I think you will all agree with me when I say that our most admired streets owe their beauty more to the well-kept grounds filled with fine shrubs and stately trees than to the houses, good as some of them undoubtedly are. Sherbourne would still be a beautiful street if the best houses were replaced by well-designed cottages costing even less than $2,000 each, while such streets as Brunswick avenue (it is mostly always avenue) would remain dreary looking if the closely-packed houses had been doubled in cost.

As architects, therefore, we have nothing to gain and much to lose by despising the low-cost dwelling as unworthy of serious attention. Though there is certainly "no money in it" for the architect, there is every other consideration to engage the best efforts of the best men. If we could imagine this a city of houses of good architectural treatment, each house standing free and, if you will, costing less than $3,000, how vastly would it be improved? If this is true of the whole, I may claim it is even more true of a part, for the part would have the advantage of contrast; and, therefore, every house of the kind that is built and turns out to be a success, is an example worthy of being followed, though not copied, and is a distinct gain to the taste of the town, out of all proportion to the importance of the building itself.

I shall not attempt to indicate what may be good or bad in the arrangement or plan of the house, as much will depend upon the habits and tastes of the occupants. I will say, however, that there should be a conservatory, no matter how small. The common idea is that this is an expensive affair both to build and to maintain. If small, the cost will be slight, and if the heating of the house is by hot water the conservatory will add little if any to the coal bill, and if by furnace, a simple coil can be arranged and operated without additional firing.

The purpose of this paper is to combat the tendency of the time to overdo the exterior of dwellings. People call them "residences" in the spirit which prompts them to name the streets and roads "avenues." As architects we cannot escape responsibility on the ground that our clients demand huge Romanesque arches and a profusion of meaningless carvings. Nevertheless we know to our cost, or even more, to our disgust, that we are not free agents, and that is why it is so much more difficult to practice than to preach. Still, there is nothing like knowing what we should do, even if we cannot often do as we ought, and I shall here briefly attempt to say what I think should be the characteristics of the building in question.

Whatever the materials of construction they should be rationally and truthfully used. There must be no imitations. The treatment should be temperate, having the true domestic feeling, with broad surfaces and deep shadows. The surfaces may be relieved by telling though not overworked detail in windows, recessed balconies, roomy porches, or a combination of verandah and porch. The entrance should be hospitable-looking, and no feature lends itself more happily to this end than the open porch with its roof a continuation of the main roof lines of the house. The great aim should be to get a good roof sheltering the whole, its bold lines and sparingly broken surfaces giving character to the design. It may be truly said that a really clever roof effect will make a success where without it all is lost.

In this country care must be taken to see that the snow will not lodge in long or shaded valleys, or slide directly upon the steps or walks or on the conservatory roof. No convenience or wholesomeness of the plan should be sacrificed to exterior effect. It is perhaps superfluous to say so, for decidedly the best design is that in which the outside effect grows out of and emphasizes the qualities within, like the face of a man who is devoted to good works. The treatment should suggest coolness in summer and comfort in winter—the former by its deeply shaded porch, balcony and eaves, the latter by its aspect in relation to the hours of sunshine by its spacious chimneys rising from the ground and locating the cheerful open fires in rooms where sunlight and a pleasant outlook are not unprovided for. Both these effects are enhanced by not having too large or too many windows.

There is nothing so good for our climate as the weighted sash window—and I say so after having earnestly tried to work out casements to open either inward or outward. It does not interfere with inside or outside shutters or storm sashes, and admits of moderate ventilation with the minimum danger from drafts. Unfortunately the two-light sash window is not an ideal feature, but it is wonderful how improved is the effect if divided into comparatively small, though not too small, lights. And I have found that if plate glass is used the outlook from within is in no way impaired, if, indeed, it is not actually improved, from the fact, I suppose, that one is conscious that the glass is between oneself and the outer air, which, after all, is the truth. The outside effect of the smaller glass is certainly pleasing, is more homelike and, therefore, more architectural in relation to the subject of this paper. Let me insist, however, on the use of plate glass, except in the less important windows.

Broadly speaking, you should bend your efforts to keeping as close to Nature as you can. Make your house appear to belong to the ground and the woods, and in this connection I cannot help saying I know of nothing in art nearer to the grey of the woods than a shingled wall, softly stained! If you stay as "near the grass" as possible you will favor low ceilings and will not be frightened by the uneducated critic, whose one word is "squatty."

Though I have not said anything original, I shall be satisfied if I have left with you the feeling that I have emphasized some truths.

*Paper read before the Toronto Architectural Guild.

PERSONAL.

Mr. Benjamin Dillon, architect, of Kingston, Ont., has opened an office in Renfrew.

Mr. K. Simpson, a railway contractor, died on the 10th of February, at Halifax, from pneumonia.

Mr. E. J. Walsh, C. E., who has been engaged for some time as colonial engineer in the Leeward Islands, has returned to Ottawa.

Mr. P. A. Peterson, of Montreal, chief engineer of the C. P. R., has been selected as vice-president of the American Society of Civil Engineers.

Mr. Charles Kessell, who was the architectural superintendent of the Administration and other buildings at the World's Fair, died in Chicago on the 6th of March.

Mr. R. M. Hannaford, son of Mr. E. P. Hannaford, late Chief Engineer of the Grand Trunk Railway, has been appointed bridge engineer of the G.T.R., with headquarters at Montreal.

Mr. T. R. Johnstone, a leading spirit in the Toronto Sketch Club, and admittedly one of the cleverest young architects of the city, has removed to New York, where he hopes to find a wider field for his abilities.

At the thirteenth annual meeting of the Master Plumbers' Association of Toronto, the following officers were elected for 1896: W. J. Burroughes, president; Jas. B. Fitzsimons, 1st vice-president; Jas. Worthington, 2nd vice-president; F. W. Armstrong, recording secretary: Thos. Cook, corresponding secretary; Al Fiddes, treasurer; J. E. Knott, sergeant-at-arms.

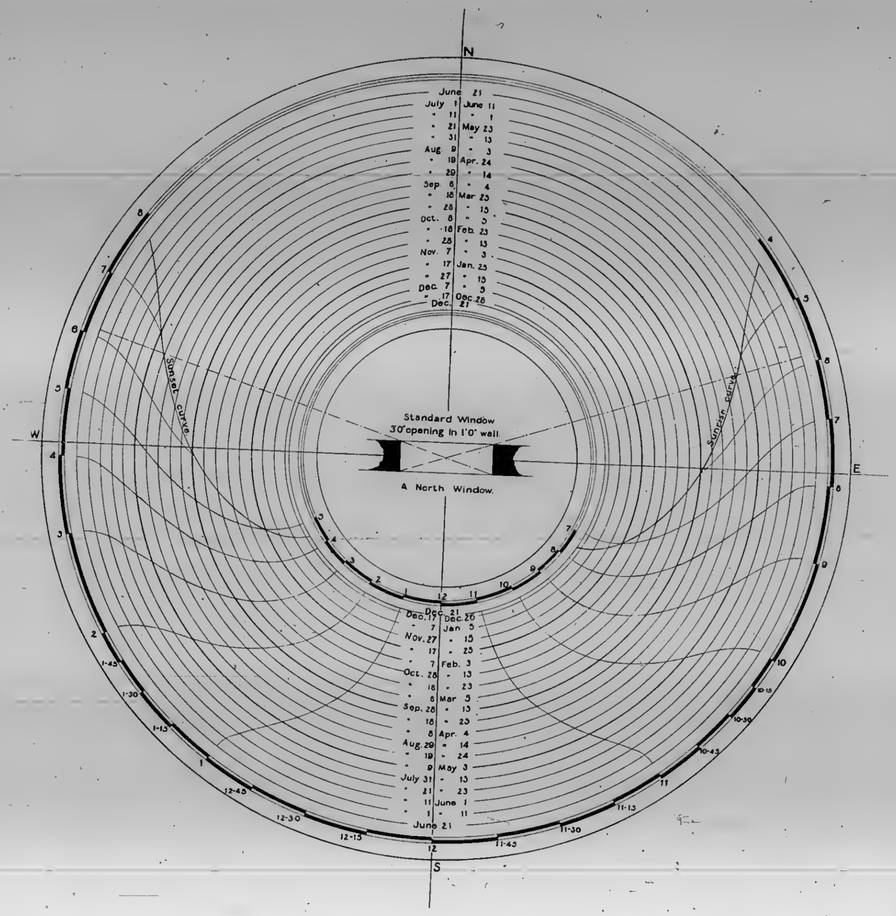
EDWARD SWALES, ARCHITECT.

PROPOSED EAST END STATION OF THE C. P. R., MONTREAL.

GEO. B. POST, ARCHITECT, NEW YORK.

TORONTO, HAMILTON & BUFFALO RAILWAY DEPOT, HAMILTON, ONT.

WM. STEWART & SON, ARCHITECTS.



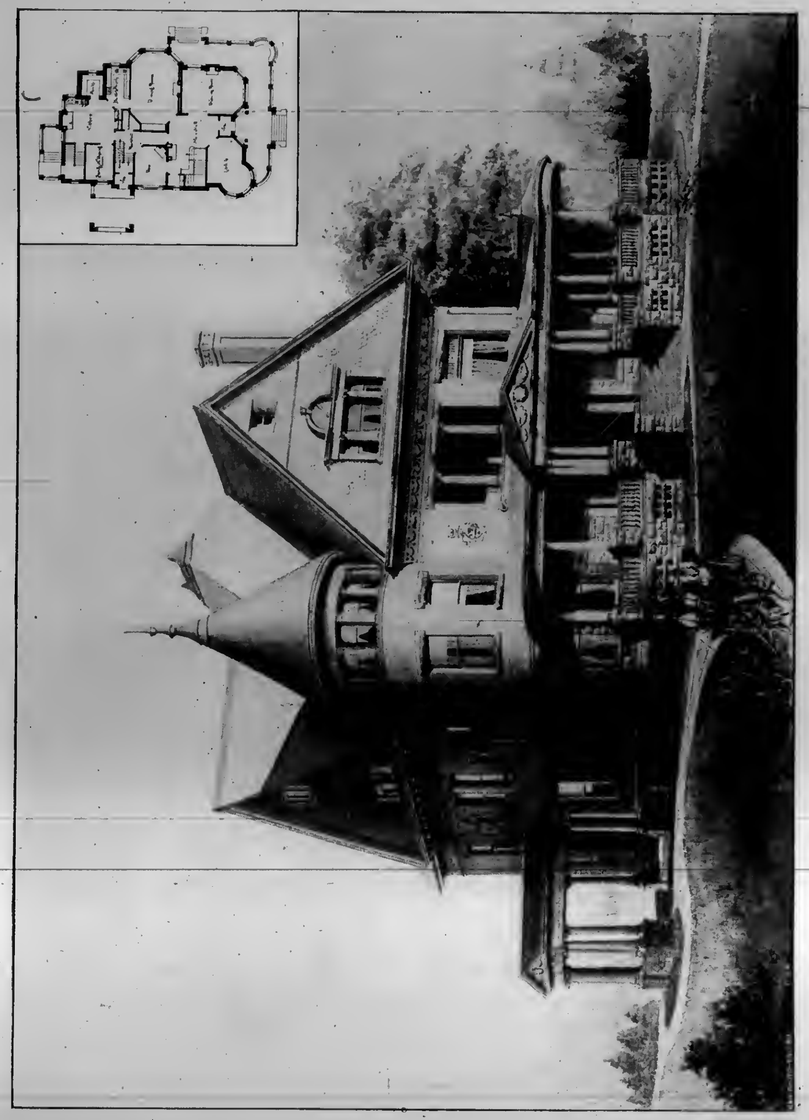
ASPECT COMPASS.

ARRANGED FOR THE LATITUDE OF TORONTO—USING APPARENT TIME.

The above compass is the one exhibited at the annual meeting of the Ontario Association of Architects by Mr. C. H. C. Wright, and gives the azimuth (direction) of the sun from sunrise to sunset for any day during the year.

Any architect, by applying a tracing of the plan of any dwelling or building to the compass, can at once determine the amount of sunlight entering through the different windows, and also the exact hours of available sunlight.

A north window is suggested in the diagram, and shows that the sun will shine through such a window on June 21st, from sunrise until nearly six o'clock in the morning, and in the evening from a little past six until sunset. Again on May 3rd or August 9th the opening will admit direct sunlight from sunrise until a quarter past five, and from a quarter to seven until sunset. After August 18th and until April 25th the sunlight will not enter the window.



RESIDENCE OF MR. F. T. FROST, SMITHS FALLS, ONT.
J. A. ELLIS, ARCHITECT, TORONTO.

CANADIAN ARCHITECT AND BUILDER.

VOL. IX.—NO. 4. APRIL, 1896 PRICE 20 CENTS $2.00 PER YEAR.

—THE—

CANADIAN ARCHITECT AND BUILDER,

A Monthly Journal of Modern Constructive Methods.

(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD).

PUBLISHED ON THE THIRD THURSDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

C. H. MORTIMER, Publisher,

Confederation Life Building, - TORONTO, CANADA.

Telephone 2362.

Branch Office: NEW YORK LIFE INSURANCE BUILDING, MONTREAL.

Bell Telephone 2299.

SUBSCRIPTIONS.

The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.

Prices for advertisements sent promptly on application. Orders for advertisemnets should reach the office of publication not later than the 12th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of technical value to the persons in whose interest this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publisher of any irregularity in delivery of paper.

ONTARIO ASSOCIATION OF ARCHITECTS.

OFFICERS FOR 1896.

PRESIDENT	H. B. GORDON, Toronto.
1ST VICE-PRESIDENT	J. GEMMELL, Toronto.
2ND VICE-PRESIDENT	JOS. W. POWER, Kingston.
TREASURER	EDMUND BURKE, Toronto.

COUNCIL:

F. J. ALEXANDER	Ottawa.
THOS. FULLER	Ottawa.
E. J. LENNOX	Toronto.
J. M. MOORE	London
W. R. STRICKLAND	Toronto

REGISTRAR AND LIBRARIAN:

W. A. LANGTON — Canada Life Building, Toronto.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.

OFFICERS FOR 1896.

PRESIDENT	A. C. HUTCHISON, Montreal.
1ST VICE-PRESIDENT	A. T. TAYLOR, Montreal.
2ND VICE-PRESIDENT	J. F. PEACHY, Quebec.
SECRETARY	J. VENNE, Montreal.
TREASURER	JOSEPH PERRAULT, Montreal.

COUNCIL:

CHAS. BAILLAIRGE	Quebec.
ROBT. FINDLAY	Montreal.
J. Z. RESTHER	Montreal.
A. H. LAPIERRE	Montreal.
G. E. TANGUAY	Quebec.
THEO. DAOUST	Montreal.

AUDITORS—A. J. FOWLER and C. CHAUSEE, Montreal.

TORONTO BUILDERS' EXCHANGE.

BOARD OF DIRECTORS:

JOHN ALDRIDGE, President.
THOS. CANNON, Jr., 1st Vice-Pres.
JOHN VICK, 2nd Vice-President.
DAVID WILLIAMS, Treasurer.
WM. BOOTH.
JOHN WICKETT.
JOHN RUSSELL.
H. LUCAS.
JOHN VOKES.
JAS. CRANG.
JOHN M. GANDER.
GEORGE HENRY.

JOHN L. PHILLIPS, Secretary.

TO ADVERTISERS.

For the benefit of Advertisers, a copy of this journal is mailed each week to persons mentioned in the CONTRACT RECORD reports as intending to build, with a request to consult our advertisement pages and write advertisers for material, machinery, etc.

The Lien Laws.

AT the last session of the Legislatures of Ontario and Quebec important amendments to the lien laws of those provinces were adopted. At the request of some of our subscribers, and to give every reader an opportunity of becoming familiar with the present existing laws, we devote considerable space in this number to the publication in full of the Ontario Lien Act of 1896, and amendments to the Auge Bill in the Province of Quebec.

The Late Lord Leighton.

By the death of Lord Leighton, England has lost one of her greatest artists and art critics. Lord Frederick was perhaps the greatest authority on the law of Harmony while alive, and his sudden taking off will be a severe loss to the whole art world. Since Ruskin has ceased to be an active factor, no man's opinion on art or its productions have been read with such deference as those given out by Leighton. He was an authority on everything he deigned to discuss.

Color in Brickwork.

THE introduction of brick of different shades, and terra-cotta, in domestic architecture, is an innovation that is to be commended if not carried beyond the limits of good taste. Fine soft effects may be obtained by a proper interweaving of different shades of bricks from the same yard, if care is taken in choosing the pattern and selecting the bricks. This sort of work, however, should only be undertaken by persons thoroughly conversant with the law of color harmony, as in unskillful hands the commingling of color would be as likely to prove disappointing as otherwise. The practice of mixing red bricks with cream-colored ones, or vice versa, is one that should be discouraged, unless the work has been designed by an architect whose good taste is beyond reproach. Many buildings in towns, villages and country in Ontario are discords in red and cream—and sometimes, in red, cream and black, with facades like immense checker boards, or covered with sheets of the Cameron tartan. We have in our mind's eye a block of stores in a northern town, well adapted for the purpose for which they were built, faultless in construction and arrangement, and modern in all their fitments, but lamentably ugly on the front exterior, partly from faulty design, but chiefly because of the use of multi-colored bricks being employed for decorative purposes over the windows and in the cornices, over-profusely, and apparently without regard to law and order.

Value of Professional Journals.

PROFESSOR Roger T. Smith, F.R.I.B.A., concluded a lecture at University College, on Architects' Libraries, by saying: "Lastly, let me recommend the back volumes of the professional journals. In the course of years all sorts of architectural topics come up in the public press and before the professional societies, and if you hunt through the indices of these publications when you are seeking for information which eludes you in books, you will often be rewarded."

The Combination of Stone with Brick.

THE introduction of stone in brick buildings always has a satisfying effect, if not overdone, inasmuch as its mission is at once recognized by the eye and accepted as being legitimate and in good taste. A fair sprinkling of greystone in plinths, beltings, quoins, lintels and sills, is not inappropriate when judiciously distributed in the walls of a red brick building. In fact, the greystone tends to soften the monotony of a continuous red surface, and gives the eye rest, while it does no violence to refined taste. Where expense does not obstruct the way, it is much better to make use of stone as an interval, than of colored bricks.

Defective Construction.

THE sudden collapse of the skeleton skating rink at Orillia recently should prove an object lesson to corporations or others owning like structures. A curling match had just been finished, and all parties, including spectators, had just left the building, when the whole affair tumbled in on the ice that had just been occupied. A little earlier, and from 75 to 100 lives would have been jeopardised; indeed, parties who were concerned in the curling game assert that had the place been occupied, nothing but a miracle could have saved a life, as tons and tons of ice fell in with the debris. Buildings of this sort, intended for public gatherings, should be under some kind of municipal or government control.

An Interesting Point of Law.

THE Courts have been called upon to give decision in a very unusual case, and one in which builders might be expected to feel an interest. Several ministers of the religious sect known as Seventh Day Adventists, who, like the Jews, observe Saturday as the Sabbath, were brought before the Courts for violating the statute relating to Sabbath observance by engaging in the work of erecting a new church in the neighborhood of Chatham, Ont., upon a Sunday. The lower courts recorded a conviction against them, and the Divisional Court at Toronto, in view of the fact that it may be desirable in the public interest to have such a question settled, refused a motion to quash the conviction. At the original hearing the defendants' counsel contended that they were not within the prohibition of the enactment, not being mechanics, or laborers, or workmen pursuing their ordinary calling.

A Chair of Architecture at McGill University.

IN connection with the recent magnificent donation of half a million dollars by Mr. W. C. McDonald to McGill University, Montreal, provision is made for the establishment of a chair and course of instruction in Architecture. We learn that there is some probability that arrangements can be made for the inauguration of this course at the next session, the necessary accommodation being provided in one of the existing buildings. This is a consummation towards which the hopes of the architects of the Province of Quebec have long been turned, and its realization has given rise to a feeling of the deepest satisfaction. As a result of the course of instruction to be established at McGill, we may expect to see the work of the architects of the future characterized by a higher standard of ability and efficiency, and from this in turn will come a truer conception and appreciation on the part of the public of the essentials of beauty.

Troubles of A German Architect.

THE London Builder tells of an architect in Berlin who lately ran foul of grief because of his endeavor to punish the city councillors for not appropriating seventy-five thousand dollars towards the building of a church in memory of the late Emperor of Germany. Because of this refusal, the architect had an inscription cut upon a bas-relief in a conspicuous place which informed the beholder that the councillors of the city of Berlin were "camels" and "too mean" to contribute anything towards the building of the church. As the legend attracted a great deal of attention the city authorities soon heard of it, and determined to retaliate. It appears that the architect stood over the artist who made the inscription during the time he was carving it; and the officials of the city, as an act of poetic justice, forced the architect to stand by while another artist cut away the obnoxious inscription. This punishment seems to have been all the authorities felt like inflicting, but the act is likely to cause some trouble, as the Berlin Institute of Architects seem to think the dignity of the profession has been insulted, and something must be done to satisfy the wounded honor.

Aesthetic Teaching in The Public Schools.

IT is gratifying to see the Honorable Minister of Education recommending the teachers in our public schools to pay more attention to the cultivation of good taste in the school room. The Minister recognizes a truism in Keats' beautiful axiom, "A thing of beauty is a joy forever," that stretches far beyond the precints of the school. Beauty, no matter in what form presented, leaves a beneficient impression on the youthful mind. The object of beauty may be a bunch of artistically arranged flowers, a picture, a painted glass window, a well-proportioned carved desk for the teacher, or a tastefully designed stove or one or more of the thousand and one things that go to make up a school's outfit. It matters not what it may be, so it is handsome in form, decoration or color; it will attract attention, and educate the eye and mind of the pupil. The school itself should be made attractive in appearance, and should be built on recognized lines of good taste, even though it be but an humble affair. By all means let us introduce into our schools all the aestheticism consistent with economy and efficient teaching. As the result of it boys will become better men, and it will add grace and dignity to the growing woman, and make life more pleasant to all concerned.

Modern Tall Building Construction.

THE modern tendency to run up buildings into the clouds is taxing the engineering abilities of our architects to their utmost. Structures ten, twelve, or twenty storeys high, require much different treatment in their foundations than do buildings with less aspirations. By this

we do not mean that a greater depth or wider footings are required than are proportionate to the weight of walls, but that other methods of procedure are necessary. A building now being erected on the corner of Broadway and Ann streets, New York, is to be twenty-six storeys above the sidewalk. A skeleton steel frame, built in with a wall four feet thick for several storeys, then three feet, then two feet, until the top is reached. These heavy walls call for a special foundation, so constructed as to meet every possible condition of settlement. This is accomplished by building under the main columns a double shoe with its two parts just alike. These shoes rest on iron rails ten or twelve feet long, bedded in concrete. There are two or three layers of these rails, according to the character of the soil, and they are laid, first, side by side, until an exact square is formed, then the next layer is placed at right angles to the first, the whole being filled in with properly tempered concrete. The space between the two legs of this double shoe is utilized for holding a powerful hydraulic jack, which is placed directly under the centre of the pier and rests in the middle of the concrete and iron foundation. The object of having the jacks placed in these openings is to be prepared to raise the building to its proper level if any displacement should ensue during construction. While the manner of using a double shoe under piers is novel, the scheme of building in hydraulic lifts is not, for if we remember rightly, a number of jacks were built in the foundations of the Marquette Building, Chicago, Ill., for the same purpose.

SOME OBJECTIONS ANSWERED.

THE Canadian Manufacturer has recently devoted considerable space to a criticism of the action of the Ontario Association of Architects in seeking legislation to restrict the use of the title "Architect" to properly qualified persons. It admits the necessity of providing some means whereby incompetent persons would be prevented from planning and supervising the construction of important buildings. It, however, finds fault with the architects for proposing, in the event of legislation being obtained, to admit into the ranks of the profession all persons who have hitherto been engaged in the practice of architecture and known by the title of architect.

In effect, the Manufacturer says to the architects, "You place emphasis on the fact that it is important that the design and construction of buildings should only be entrusted to qualified men, and that you are desirous of raising the standard of architectural practice, but at the same time you propose to allow every man now practicing as an architect, no matter how incompetent he may be, to continue to call himself an architect and to design and erect buildings as he has been accustomed to do heretofore."

Will the Manufacturer give us a better method of raising the standard of architectural practice than the one proposed by the promoters of this Bill? The architects are simply doing the best they can under the circumstances. If they were to ask for the exclusion from the profession of every person now practicing as an architect who should not be able to pass a certain qualifying examination, we are quite safe in saying that the Legislature would not consider for a moment their application. It would at once see the injustice which would result to men who have spent years in the practice of architecture, if they were compelled, perhaps beyond the period of middle life, to abandon their calling or at least to pursue it under a different name. Seeing that it would not be possible to obtain legislation by which the standard of the profession might immediately be raised to the desired level, the architects have wisely adopted the more moderate course of asking for legislation by means of which the standard could gradually be raised. If the desired legislation were obtained, the number of incompetent architects would for a time remain as at present, but the door would be closed to additions to their ranks, and the coming generation of architects would be compelled to undergo a proper course of study and pass the necessary examinations to qualify them for the proper discharge of their duties.

The situation may briefly be stated thus: If the standard of architectural practice is ever to be raised, a start must be made in that direction, and if means cannot be found to immediately raise the standard to the required level, the architects are surely not deserving of censure for adopting a course whereby that object may be gradually attained.

ONTARIO ARCHITECTS' ACT.

WE regret to state that the Ontario Architects' Bill in the Ontario Legislature has again been withdrawn. The majority of the members of the Committee expressed themselves as having no personal objection to the measure, and the Bill was reported by the Committee to the House. The mover of the Bill deemed it wise, however, to withdraw it for the present, believing that the feeling of the House was not sufficiently favorable to insure the passage of the measure, and that the longer it is kept before the House the better its objects will be understood and the more probable will be its final adoption.

One of the strongest opponents of the Bill was the speaker of the House, who announced himself as being opposed on general principles to all such legislation, while unable to give any specific and satisfactory reasons for his opposition. He even went so far as to lobby against the Bill, a most unusual and undignified proceeding.

The great obstacle in the way of the measure appeared to be the inability of the legislators to understand the object which the architects had in view in seeking to obtain this legislation. They seemed to take it for granted that there must be on the part of the architects a personal object to be gained, and because they could not discover such an object they regarded the Bill with suspicion. In view of the suspicion in which the efforts of the architects are held and their methods questioned, it were much better that the legislation sought should be promoted by persons entirely outside of the profession. There are a large number of persons who thoroughly understand the necessity for such legislation as will elevate the standard of architectural practice in this province, and we believe it would be possible to obtain an influentially signed petition asking the Government to legislate on the question. The Government appears to be thoroughly in accord with the objects of the Bill, and we would be pleased if they could see their way introduce a Government measure dealing with the question.

A great many architects and builders now ride wheels, as they are found to be cheaper and more convenient than the regulation horse and buggy. The Vokes Hardware Co., Toronto, announce that they are sole Canadian agents for the Ben-Hur wheel, which has won for itself an excellent record. A catalogue giving full particulars may be had on request to the company.

SANITATION AND HEALTH

TORONTO MASTER PLUMBERS AND STEAM FITTERS.

The Master Plumbers' and Steam Fitters' Association, of Toronto, was organized in the year 1885, and although including only a portion of the employers in those trades, was a fairly successful organization. During the prolonged strike of the journeymen plumbers in 1888 the Association became quite active, and embraced nearly every employing plumber in the city. Since that time, largely owing to the depression in building operations, interest in the Association has to some extent declined. An effort has therefore been made during the past winter by some of the members to infuse new life into it, which effort has been successful.

To promote good fellowship and bring the members into closer touch with one another, the idea of an annual banquet was conceived. The event took place on Thursday evening, the 26th of March, and the success which attended it augurs well for the future of the Association. Shortly after eight o'clock the members and their friends, with business cast aside and wearing smiling countenances, put in an appearance at Webb's restaurant. Upwards of one hundred occupied seats at the table, among whom were many prominent plumbers of the city, representatives of the wholesale supply houses, civic representatives, and visitors from London.

As the jovial company took their seats around the festive board, there was no evidence to be seen of the hard times through which those connected with the building trades in Toronto have passed.

The members of the Association, nearly all of whom were present, are as follows :

W. J. Burroughes.	A. G. McCauley.
J. B. Fitzsimons.	W. H. Hewlett.
Thos. Worthington.	K. J. Allison.
F. W. Armstrong.	Geo. Wallace.
Thos. Cook.	P. J. LeCour.
A. Fiddes.	J. R. Seager.
J. E. Knott.	A. B. Webster.
Jas. Wilson.	Jas. Sherlock.
Jos. Wright.	Geo. Guest.
John Wright.	A. Cruickshank.
John Sim.	J. Aggett.
H. Hogarth.	W. Mansell.
Fred Armstrong.	A. Purdy.
W. J. McGuire.	W. Mashinter.
W. J. Guy.	D. Clark.
C. H. Beavis.	J. H. Parkes.
T. Gordon.	J. Harkley.
Wm. Erwood.	J. Monahon.
S. Meadows.	John Ross.
W. M. Watson.	Thos. Slean.
H. Richards.	R. Ross.
J. W. Oram.	Geo. McGuire.
J. H. Cairns.	

In addition to the members of the Association present, the following were noticed : W. F. McLean, M.P.; Ald. Hallam ; Ald. Bell ; Ald. McMurrich ; P. McMichael and Mr. Miller, of the Jas. Robertson Co. ; W. H. Carrick and T. B. Alcock, of the Gurney Foundry Co. ; Assistant City Engineer Rust ; Fred. Somerville, of the Ontario Lead and Barb Wire Co. ; A. D. MacArthur, of Craig, MacArthur & Co. ; H. W. Anthes, Toronto Foundry Co. ; W. J. Skelley, London; Mr. Smith, of Smith Bros., London ; W. J. Hazlett, London ; Mr. Stevens, London ; John Ritchie, Toronto; A. Fiddes ; W. B. Malcolm ; Robt. Fair ; James Morrison, of the James Morrison Co. ; W. C. Bullock, of John Perkins & Co. ; James Malcolm, of the Ontario Lead and Barb Wire Co. ; Andrew Taylor, of the Toronto Radiator Co. ; John Wayne, of the Polson Co., John Aldrich, president of the Builders' Exchange.

The President's chair was occupied by Mr. W. J Burroughes and the vice-chair by Mr. J. B. Fitzsimons.

After justice had been done to the menu, the President extended a few words of welcome to the members and their friends, and while feeling grateful for the large number present, expressed the hope that next year might witness an even larger gathering.

He then read letters of regret from the following : Mayor Fleming, City Engineer Keating, Medical Health Officer Sheard, Ald. Boustead, Lamb, Burns ; John M. Taylor, of the Toronto Radiator Co. ; Mr. Lamarche, president of the Montreal Master Plumbers' Association; J. W. Hughes, secretary Montreal Plumbers' Association ; Fairly & Stewart, Hamilton ; Adam Clark, Hamilton ; Everson & Hawkins, Oshawa ; John Boston, president Halifax Association ; Adam Hall, Peterboro ; Stevens Manufacturing Co., London ; Mr. McAvity, St. John ; Bennington & Bain, Windsor, Ont. ; John

MR. W. J. BURROUGHES,
President Toronto Master Plumbers' and Steam Fitters' Association.

McKinley, president of the Ottawa Association ; McKelvey & Birch, Kingston ; H. Dakin, Galt ; Steel Clad Bath Co.

Attention was next directed to the toast list. "The Queen and Royal Family," was responded to by the company singing the national anthem.

The toast of the "Lieutenant-Governor and Parliament of Canada," brought Mr. W. F. McLean, M. P., to his feet. He apologized for so much time being taken up by Parliament in discussing a question affecting race and creed, and thought the development of the resources of our country should receive more consideration. "Last week," he remarked, "we were in session night and day, and I am sorry we had not a master plumber among us to charge double price for over-time. Your Association is formed to regulate prices and make a living profit, and I believe every Association thus formed should be supported. I therefore congratulate this Association, and wish it prosperity."

"The Maple Leaf Forever," was sung in honor of the toast "Canada Our Home."

With the toast "The Mayor and Corporation of Toronto," the President coupled the names of Ald. McMurrich, Bell and Hallam.

Ald. McMurrich declared that plumbers came next to doctors in his estimation. The public, as a rule, did not give sufficient attention to plumbing. The alderman referred to the movement to transfer the plumbing department to the control of the Medical Health Officer,

and expressed the hope that the change would prove beneficial.

Ald. Hallam followed, and took occasion to make a hit at the plumber's bill. "If you get as good returns from your banquet as you do from your bills," he said, "you will have enough to keep you feasting until the end of the world." Regarding legislation he promised his support to any movement which is in the interest of the public, and he had confidence that the plumbers will only ask for what is right.

Ald. Bell said he had always coincided with the views of the plumbers, and declared that the amendments to the Plumbers' By-law, which were secured at the solicitation of the plumbers, had resulted beneficially to the public.

The toast of the "Manufacturers and Wholesale Supply Men," was proposed by the Vice-President, and the manner in which it was received showed that little friction existed between the plumbers and manufacturing firms.

Mr. Carrick, of the Gurney Foundry Co., was the first to respond. He regretted the unavoidable absence of their president, but assured the members of the Association that his firm would do all in their power to meet the demands of the trade.

Mr. James Morrison congratulated the Association upon the success of their banquet, and expressed himself as willing to assist in improving the plumbing trade.

Mr. P. McMichael, of the James Robertson Co., was satisfied that the Association had the sympathy of the manufacturers, who, he believed, would do everything in their power to place the trade on a solid financial basis.

The next response came from Mr. W. B. Malcolm, who said : "Within the past few years conditions in the plumbing trade have greatly changed. Some time ago it was necessary to keep a number of men to make up baths, soil pipe, etc., but now this has passed into the hands of the manufacturers, and the plumber has very little for his men to do. This has brought about keen competition, and prices are therefore cut very fine. It is necessary that the manufacturers should join with the plumbers to maintain prices. In this way the manufacturers would be benefitted, as there would be fewer failures."

Mr. Somerville, of the Ontario Lead and Barb Wire Co., also promised the Association the sympathy and co-operation of his firm.

Mr. MacArthur, of Craig, MacArthur & Co., said : The progress and growth of the plumbing trade is one of the wonders of civilization. No man works harder and receives less remuneration for his services than the plumber, except, perhaps, the supply man. Instead of plumbers receiving more than a just amount for their work, it is quite the reverse. Show me a retired plumber. They are not to be found, but in nearly every other trade or profession it is possible to retire after fifteen or twenty years of active business.

Mr. Andrew Taylor, of the Toronto Radiator Company ; Mr. Stephens, of London ; Mr. Wayne, of the Polson Co. ; Mr. Anthes, of the Toronto Foundry Co. ; and Mr. Bullock, of the Perkins Boiler Works, each spoke briefly, complimenting the Association and promising their hearty support.

With the toast of "Our Guests" were coupled the names of three representatives from London, Messrs. Hazlett, Skelly and Smith.

Mr. Hazlett said that they had tried three or four times to form an Association in London, but without success, and now they were going to make another attempt. They had come down to the banquet to get some ideas, and he hoped next year he would be able to return the courtesy of an invitation.

Mr. Smith and Mr. Skelley also made some brief remarks, referring to the difficulty experienced in forming an Association in London.

The President then invited all the members of the Master Plumbers' and Steam Fitters' Association to meet the London delegates at the Builders' Exchange at 10 o'clock the following morning, for the purpose of discussing the formation of an Association in London.

Mr. John Aldrige, President of the Toronto Builders' Exchange, responded to the toast of "Sister Associations" in a few brief but pointed remarks. He hoped the plumbers would shortly form a provincial Association.

Messrs. Kirk and Meadows replied to the toast of the "Plumbing Inspectors of Our City," and Messrs. Alcock and Meadows to that of "The Ladies." "The Press" was acknowledged by representatives of Hardware and Metal and the Canadian Architect and Builder.

Although the hour was late, the opportunity of drinking the health of the Association was not allowed to pass. The toast was proposed by Mr. MacArthur, in response to which the President, Mr. Burroughes, expressed regret that there were so many illegitimate plumbers in the city of Toronto. He believed that membership in the Association should be sufficient qualification for a plumbing license, and no man should be given a license who could not pass a qualifying examination. He intended to use his efforts to improve the trade. (Cheers.)

The Vice-President and Secretary-Treasurer were also called, and expressed their belief in the possibility of bringing about an improved condition of the trade.

The entertainment feature of the evening's programme was as follows : Songs by Messrs. Bullock, Alexander, Ernest Williams, John Ritchie, R. J. Hazlett, Beavis and Ald. McMurrich ; comic speech by Mr. Palmer ; humorous reading by Mr. James Malcolm ; ventriloquism, Mr. Simpson.

The committee of management, composed of W. J. Burroughes, Jas. H. Wilson, Thos. Cook and G. H. Beavis, have every reason to feel gratified at the success which attended their efforts.

TRANSFER OF PLUMBING DEPARTMENT.

In the recent reconstruction of the various civic departments of Toronto, the Plumbing Department was transferred from the supervision of the City Engineer to that of the Medical Health Officer. The plumbing trade regard the new arrangement with favor, as likely to result beneficially to the city, the plumber, and the general public. In this connection we might state that it is the intention of the master plumbers to seek certain amendments to the existing city plumbing by-law. The main object of these amendments is to secure for the license inspectors more freedom in the exercise of their judgment. It is held that the present by-law is so framed that the inspectors are bound down to cast-iron rules, without regard to the governing conditions in any particular case. With competent inspectors it seems reasonable to expect that they should be allowed the free exercise of their knowledge, and this the plumbers hope to secure under the new order of things.

The Halifax Master Plumbers' Association have adopted resolutions for the protection of the trade, and have forwarded a copy of same to every manufacturer of plumbing supplies in Canada.

The members of the Toronto Master Plumbers' Association held a conference at the Builders' Exchange, Toronto, on the 28th of March, with representative master plumbers of London, Ont., to discuss the organization of an Association in the latter city. The London delegates were Messrs. W. J. Skelly, W. J. Hazlett and W. Smith, who were furnished with copies of the constitution and full information regarding the working of the Toronto Association. It is believed that at an early date the formation of an Association in London will be accomplished.

STUDENTS' DEPARTMENT.

"CANADIAN ARCHITECT AND BUILDER" STUDENTS' AND DRAUGHTSMEN'S COMPETITION.

THE publisher invites from architectural students and draughtsmen, other than practising architects, designs for front cover page for the New Year (1897) Number of the CANADIAN ARCHITECT AND BUILDER.

Designs must be rendered either with pen and perfectly black ink or with brush in sepia on a sheet of white drawing paper or card-board, drawn to the size or 22 × 14 inches, and capable of being reduced to 7 × 11 inches. The wording to appear on the design is as follows:

"CANADIAN ARCHITECT AND BUILDER.
NEW YEAR NUMBER. 1897. TORONTO, CANADA."

Drawings must be marked only with the motto of the author, and accompanied by the motto, full name and address of the author, in sealed envelope, must be sent, charges paid, addressed to the publisher of the CANADIAN ARCHITECT AND BUILDER, Toronto, so as to reach this office on or before 5 o'clock p. m. on Monday, the 6th of June next.

This competition will be decided by a majority vote of a committee of architects to be appointed for that purpose by the Council of the Province of Quebec Association of Architects and of the Ontario Association of Architects. The decision of this committee will be final.

If two or more suitable designs are submitted a prize of $10.00 will be given to the author of the one awarded first position and $5.00 to the one awarded second place. The right is reserved to withhold the prizes if two or more suitable designs are not submitted. The right is also reserved to publish any of the designs submitted.

NOTE.—This competition is announced with the object of testing somewhat outside of the lines of their every day work the artistic skill of Canadian students and draughtsmen. It is hoped that the response will be generous and earnest, and the result satisfactory.

SKETCHING COMPETITIONS IN THE SECOND CLASS OF THE SCHOOL OF FINE ARTS, PARIS.

By I. O. MARCHAND.

"Au quel entrain et quelle 'emulation!" If these competitions have provoked this sincere expression, fallen from the lips of the celebrated "patron" of H. H. Richardson, I feel assured that I am dealing with a subject that has interested to the utmost, scores of young artists.

These competitions, which last twelve hours and are made "en loge," that is in one of the spacious class rooms of the school, divided into compartments to accommodate but one pupil, take place every two months, and have for object to develop the artistic sense of the pupils and to train them in grasping in as short a time as possible the spirit of a program and of a "plan parti" (standard plan.)

At 9.30 a. m. the pupils are closeted in the loges and at 10 o'clock the program which has been prepared by the professor of theory, Monsieur Guadet, who replaces Monsieur Guillaume, is distributed; immediately every pupil's attention is concentrated on the program before him, and each endeavours to find a plan or the standard plan if not the solution of the program. If the programme calls for an interesting facade such as that required for a museum or an atheneum, the plan is worked on the breadth; if, on the contrary, the plan requires several dispositions on the axis, such as is required in an insane asylum or a thermal establishment, the plan is worked on the length.

With this as a starting point we commence by grouping the plan, studying it in detail and scaling the sizes of the different rooms required, and then a clear tracing of it is made, bringing out the most important motives of construction, till the last study presents a satisfactory arrangement and an harmonious whole, after which we pass on to the facade which sometimes is of minor importance in the programs of Monsieur Guadet.

Formerly under the direction of Monsieur Guillaume the "esquisses esquisses" as they are called at the school, possessed a more artistic sense in themselves, in that less importance was attached to the plan, and their merit consisted mainly in the beauty and rendering of the studies of the facade; but all this had the inconvenience of rendering the sketches devoid of cleverness, and of offering nothing interesting judged from the research point of view; a rendering had but to be well done and effective and one could count upon a mention. This came to an end with the Guadet regime—all the spirit of the program resting on the study of the plan and of its arrangements—and for my part I think the last mentioned is more logical, in that they form a sort of introductory exercise to pass into the first class where the real drill in design and the serious study of planning begins.

Once the studies are completed, the final rendering is taken up, and here commences the amusing part of the competition. From all sides is heard the cries of "charrette charrette!" which indicates that the time for closing is drawing near. Those who take part in the competition for the first time get discouraged and abandon it, while the most presevering work steadily at it in their loge. The most clever get through before the appointed time, but every one feels nervous, and soon the guardian shouts "on ferme! on ferme!"—(closing! closing!)—and all competitors run in the direction of the guardian-in-chief to deliver to him his "projet," whether completed or not.

The sketches are then exhibited in the Melpomene Hall, where every pupil goes for a week to compare his "projet" with that of other competitors. Sometimes it loses in interest considerably, by its smallness of scale and its arrangement as a whole, and also by the "parti" adopted, by indication, and by the rendering.

These exhibitions do a good deal towards the advancement of the pupils and teach them many lessons. For my part I have been many a time disappointed by the showing of my "projet" when placed side by side with those of other competitors; while it seemed satisfactory enough when in the loge, it lost in value either by its smallness and meanness or by its lack of air when exhibited.

The competitions are judged by the heads of "ateliers." Of two hundred pupils who commence the "projet," only about one hundred render, while seven or eight only succeed in obtaining a mention, which mention counts as a value for admission into the first class.

I hereunder give one of the recent programs proposed by Monsieur Guadet, for "A Parishional Church" accompanied on separate sheet by the sketch submitted by myself, which will convey an idea to the readers of the "CANADIAN ARCHITECT AND BUILDER of the nature of these "esquisses esquisses" as practised in the school. The sketches are generally rendered in pencil and color or washed, but a rough tracing in black and white had in this instance to be made in order to publish it in this journal.

EMULATION COMPETITION OF THE 4TH DECEMBER, 1895.—"A PARISHIONAL CHURCH."

This church erected in a fashionable quarter of a large city, would comprise a nave, aisles and chancel, with or without transept; numerous chapels for particular services, and one principal chapel of the Holy Virgin; two vestries, one for the clergy and marriages, and the other for attendants of the church: organ tribune. The accommodation for the catechism class, the members of the choir, etc, would be in the basement. The church can be preceded by a porch forming carriage way, and will also have side entrances, and one or two spires. The ceiling will be vaulted and the roof will be entirely built above the vaulting.

The ground available for this church which is isolated on all sides, has for largest dimension (length) 120 metres (365 feet). The plan, transverse section (parallel to facade) and facade will be made to the scale of 0.00015 to the metre.

J. GUADET,
Professor of Theory.

Paris, 4th December, 1895.

Mr. John Shanklin, a well-known contractor, who had resided in Toronto for sixty-three years, died at his home a fortnight ago. Deceased was born in Ireland in 1827, and came to Toronto when six years of age.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

CANADIAN SOCIETY OF CIVIL ENGINEERS.

An ordinary meeting of this Society was held on March 12th, the President, Mr. Herbert Wallis, in the chair.

The following were elected into the Society:—Associate members—Walter Jos. Francis, Deer Park, Ont.; John W. Harris, Winnipeg, Man. Students—William J. Bishop, Montreal; Hamilton Lindsay, Kingston, Ont. The following were transferred from the class of student to the class of associate member:—John Edward Schwitzer and Alex. W. Spence, Ottawa; Alfred J. Stevens, Moncton, N. B.

At this meeting the discussion on Mr. W. Bell Dawson's paper on "A New Method for the Design of Retaining Walls" was continued, and a paper on "The Effects of Engineering Works on Water Currents," by Cyrus Carroll, M. Can. Soc. C. E., was read.

At the ordinary meeting of the Society held on the 26th of March, the President, Mr. Herbert Wallis, occupied the chair. The evening was taken up in the discussion of the resolution: "That engineering works shall be constructed by day's work under the immediate direction of a civil engineer, instead of being done through a contractor."

THE AUGE BILL.

By request of a number of subscribers to the ARCHITECT AND BUILDER, I forward herewith for publication a copy of the amendments to the Auge Bill passed at the last session of the Quebec Legislature, as follows:—

1. Paragraph 7 of article 2,009 of the Civil Code, as replaced 57 Victoria, chapter 46, section 1, is replaced by the following:

"7. The claim of the laborer, workman, architect and builder, subject to the provisions of article 2,013.

2. Articles 2013, 2013a, 2001 3b, 2013c, 2013d, and 2013e of the said Code, as enacted by section 2 of the said act, is replaced by the following:

"2013. The laborer, workman, architect and builder have a right of preference over the vendor and other creditors, on the immoveable, but only upon the additional value given to the immoveable by the work done.

In case the proceeds are insufficient to pay the labor, workman, architect and builder, or in cases of contestation, the additional value given by the work is established by a relative valuation effected in the manner prescribed in the Code of Civil Procedure."

The aforesaid privileged claim is paid only upon the amount established as being the additional value given to the immoveable by the work done.

"2 013a. The privilege of the laborer, workman, architect and builder ranks as follows:

1. The laborer;
2. The workman;
3. The architect;
4. The builder.

"2013b. The right of preference or privilege upon the immoveable exists as follows:

1. Without registration of the claims in favor of the debt due the laborer, workman and the builder, during the whole time they are occupied at the work or while such work lasts, as the case may be; and with registration, provided it be registered within the thirty days following the date upon which the building has become ready for the purpose for which it is intended.

2. But such right of preference or privilege shall exist only for one year from the date of the registration, unless a suit be taken in the interval, or unless a longer delay for payment has been stipulated in the contract.

"2013c. The preservation of the privilege is subject to the following conditions:

1. The laborer or workman must give notice in writing or verbally, before a witness, to the proprietor of the immoveable that they have not been paid for their work at and for each term of payment.

Such notice may be given by one of the employers in the name of all the other laborers and workmen who are not paid, but in such case the notice must be in writing.

2. The architect and builder shall likewise inform the proprietor of the immoveable or his agents in writing of the contracts which they have made with the chief contractor, within eight days from the signing of the same.

"2013d. In order to meet the privileged claims of the laborer and workman, the proprietor of the immoveable may retain an amount equal to that which he has paid or will be called upon to pay, according to the notices he has received, so long as such claims remain unpaid.

"2013e. In the event of a difference of opinion between the creditor and the debtor, with respect to the amount due, the creditor shall, without delay, inform the proprietor of the immoveable, by means of written notice which shall also mention the name of the creditor, the name of the debtor, the amount claimed, and the nature of the claim.

The proprietor then retains the amount in dispute until notified of an amicable settlement or a judicial decision."

"2013f. The sale to a third party by the proprietor of the immoveable or his agents, or the payment of the whole or a portion of the contract price cannot in any way affect the claims of persons who have a privilege under article 2013, and who have complied with the requirements of articles 2013a, 2013b, 2013c, and 2103."

"2,013g. The supplier of materials shall, before delivery of the materials, give notice in writing to the proprietor of the immoveable, of the contracts made by him for the delivery of materials, and mention the cost thereof and the immoveable for which they are intended.

"2013h. In order to meet the privileged claims of the suppliers of materials, the proprietor of the immoveable retains, on the contract price, an amount equal to that mentioned in the notices he has received.

"2013i. The notices mentioned in article 2,013g have the effect of an attachment by garnishment on the contract price.

Within the three months following the notice given in accordance with article 2,013a, the interested parties must adopt legal steps, by proceeding against the proprietor of the immoveable, to have the debtor condemned and the seizure declared valid, otherwise the latter lapses.

"2013j. In the event of the proprietor of the immoveable erecting the building himself without the intermediary of any contractor, the notices mentioned in article 2013g may be given to the person or persons who lend or may lend money to the person building, and thereupon the latter shall, mutatis mutandis, be subject to the provisions of the preceding articles.

"2013k. No transfer of any portion of the contract price or of the amount borrowed, as the case may be, either before or during the execution of the work, can be set up against the said suppliers of materials; nor can any payment, exceeding the costs of the work done according to a certificate of the architect or superintendent of the works, affect their rights.

"2013l. On notice given to the proprietor in virtue of article 2013g, and registered according to article 2103, the suppliers of materials shall have a hypothecary privilege which shall rank after the hypothecs previously registered and the privileges created by this act."

3. Articles 2103 and 2103a of the said Code, as enacted by section 3 of the said act, are replaced by the following article:

"2103. The privileges of the persons mentioned in article 2013 dates, in the cases mentioned in the first clause of article 2013b, only from the registration, within the proper delay, at the registry office of the division in which is situated the immoveable affected by the inscription, of a notice or memorial, drawn up according to form A, with a deposition of the creditor, sworn to before a justice of the peace or a commissioner of the Superior Court, setting forth the nature and the amount of the claim, and describing the immoveable so affected.

(Concluded on Page 56)

THE ONTARIO LIEN LAW OF 1896.

AN Act was passed by the Ontario Legislature at the recent session making certain amendments and additions to the lien law respecting mechanics, wage earners, and others. Below will be found the Act in full as revised :

1. This Act may be cited as THE MECHANICS' AND WAGE-EARNERS' LIEN ACT, 1896. R.S.O. 1887, c. 126, s. 1.

2. Where the following words occur in this Act, or in the schedules hereto, they shall be construed in the manner hereinafter mentioned, unless a contrary intention appears :

(1) "Contractor" shall mean a person contracting with or employed directly by the owner or his agent for the doing of work or placing or furnishing materials for any of the purposes mentioned in this Act.

(2) "Sub-contractor" shall mean a person not contracting with or employed directly by the owner or his agent for the purposes aforesaid, but contracting with or employed by a contractor, or under him by another sub-contractor.

(3) "Owner" shall extend to and include any person, firm, association, body corporate or politic, including a municipal corporation and railway company having any estate or interest in the lands upon or in respect of which the work or service is done, or materials are placed or furnished, at whose request and upon whose credit or on whose behalf or with whose privity or consent or for whose direct benefit any such work or service is performed or materials are placed or furnished, and all persons claiming under him or them whose rights are acquired after the work or service in respect of which the lien is claimed is commenced or the materials furnished have been commenced to be furnished. R.S.O. 1887, c. 126, s. 2.

(4) "Person" shall extend to and include a body corporate or politic, a firm, partnership or association.

(5) "Material" shall include every kind of moveable property.

(6) "Registry Office" shall include Land Titles Office.

3. Where work or service is done or materials are furnished upon or in respect of the lands of any married woman with the privity and consent of her husband, he shall be conclusively presumed to be acting as well for himself and so as to bind the interest, and also as the agent of such married woman for the purposes of this Act, unless the person doing such work or service or furnishing such materials shall have had actual notice to the contrary before doing such work or furnishing such materials.

4. No agreement shall be held to deprive anyone otherwise entitled to a lien under this Act, and not a party to the agreement, of the benefit of the lien, but the lien shall attach, notwithstanding such agreement. R.S.O. c. 126, s. 3.

5. Unless he signs an express agreement to the contrary, any person who performs any work or service upon or in respect of, or places or furnishes any materials to be used in making, constructing, erecting, fitting, altering, improving or repairing any erection, building, railway, land, wharf, pier, bulkhead, bridge, trestlework, vault, mine, well, excavation, fence, sidewalk, paving, fountain, fishpond, drain, sewer, aqueduct, roadbed, way, fruit and ornamental trees, or the appurtenances to any of them, for any owner, contractor or sub-contractor, shall by virtue thereof have a lien for the price of such work, service or materials upon the erection, building, railway, land, wharf, pier, bulkhead, bridge, trestlework, vault, mine, well, excavation, fence, sidewalk, paving, fountain, fishpond, drain, sewer, aqueduct, roadbed, way, fruit and ornamental trees, or appurtenances thereto, and the lands occupied thereby or enjoyed therewith, or upon which the said work or service is performed, or upon which such materials are placed, or furnished to be used, and limited in amount to the sum justly due to the person entitled to the lien and to the sum justly owing (excepting as herein provided) by the owner.

6. The lien shall attach upon the estate or interest of the owner as defined by this Act in the erection, building, railway, land, wharf, pier, bulkhead, bridge, trestlework, vault, mine, well, excavation, fence, sidewalk, paving, fountain, fishpond, drain, sewer, aqueduct, roadbed, way, fruit and ornamental trees and the appurtenances thereto, upon or in respect of which the work or service is performed, or the materials placed or furnished to be used, and the lands occupied thereby or enjoyed therewith. See R.S.O., c. 126, s 5.

(2) In c ses where the estate or interest charged by the lien is leasehold the fee simple may also, with the consent of the owner thereof, be subject to said lien, provided such consent is testified by the signature of such owner upon the claim of lien at the time of the registering thereof, and duly verified. R.S.O. 1877, c. 126, s. 5, s.s. 2.

(3) In case the land upon or in respect of which any work or service is performed, or upon or in respect of which materials are placed or furnished to be used, is encumbered by a prior mortgage or other charge, and the selling value of the land is increased by the work or service, or by the furnishing or placing of the materials, the lien under this Act shall be entitled to rank upon such increased value in priority to the mortgage or other charge. R.S.O. 1877, c. 126, s. 5, s.s. 3.

(4) The provisions of this or any other section of this Act affecting railways under the control of the Dominion of Canada are only intended to apply so far as the Legislative Assembly of this Province has authority or jurisdiction in regard thereto.

7. Where any of the property upon which a lien is given by this Act is wholly or partly destroyed by fire, any money received by reason of any insurance thereon by an owner or prior mortgagee or chargee shall take the place of the property so destroyed, and shall be subject to the claims of all persons for liens to the same extent as if such moneys were realized by a sale of such property in an action to enforce a lien.

8. Save as herein provided the lien shall not attach so as to make the owner liable for a greater sum than the sum payable by the owner to the contractor. R.S.O. c. 126, s. 10.

9. Save as herein provided where the lien is claimed by any other person than the contractor, the amount which may be claimed in respect thereof shall be limited to the amount owing to the contractor or sub-contractor or other person in for whom the work or service has been done or the materials have been placed or furnished. R.S.O. 126, s. 8.

10.—(1) In all cases an owner shall, as any contract progresses, deduct from any payments to be made, and retain for a period of thirty days after the completion or abandonment of the contract twenty per cent. of the value of the work, service and materials actually done, placed or furnished as defined by section 5 of this Act, and such values shall be calculated on the basis of the price to be paid for the whole contract; provided that where a contract exceeds $15,000 the amount to be retained shall be fifteen per cent. instead of twenty per cent., and the liens created by this Act shall be a charge upon the amounts directed to be retained by this section.

(2) All payments up to eighty per cent. (or eighty-five per cent. where the contract price exceeds $15,000 of such value made in good faith by an owner to a contractor, or by a contractor to a sub-contractor, or by one sub-contractor to another sub-contractor, before notice in writing of such lien given by the person claiming the lien to the owner, contractor or the sub-contractor, as the case may be, shall operate as a discharge pro tanto of the lien created by this Act.

11. In case an owner or contractor chooses to make payments to any persons referred to in the fifth section of this Act for or on account of any debts justly due to them for work or service done or for materials placed or furnished to be used as therein mentioned, and shall within three days afterwards give, by letter or otherwise, written notice of such payment to the contractor or his agent, or to the sub-contractor or his agent, as the case may be, such payments shall, as between the owner and the contractor or as between the contractor and the sub-contractor, as the case may be, be deemed to be payments to the contractor or sub-contractor, as the case may be, on his contract generally, but not so as to affect the percentage to be retained by the owner, as provided by section 10 of this Act.

12.—(1) The lien created by this Act shall have priority over all judgments, executions, assignments, attachments, garnishments and receiving orders recovered, issued or made after such lien arises, and over all payments or advances made on account of any conveyance or mortgage after notice in writing of such lien to the person making such payments or after registration of such lien as hereinafter provided. (See 56 Vic., c. 24, s. 4 and R.S.O. c. 126, s. 31.)

(2) In case of an agreement for the purchase of land, and the purchase money or part thereof is unpaid, and no conveyance made to the purchaser, the purchaser shall, for the purposes of this Act and within the meaning thereof, be deemed a mortgagor and the seller a mortgagee.

(3) Excepting where it is otherwise declared by this Act, no person entitled to a lien on any property or to a charge on any moneys under this Act shall be entitled to any priority or preference over another person of the same class entitled to a lien or charge on such property or moneys under this Act, and each class of lien holders, except where it is otherwise declared by this Act, shall rank pari passu for their several amounts, and the proceeds of any sale shall, subject as aforesaid, be distributed among them pro rata according to their several classes and rights.

13.—(1) Every mechanic or laborer whose lien is for work done for wages shall, to the extent of thirty days' wages, have priority over all other liens derived through the same contractor or sub-contractor to the extent of and on the twenty per cent. or fifteen per cent., as the case may be, of the contract price directed to be retained by section 10 of this Act, to which the contractor or sub-contractor through whom such lien is derived and entitled, and all such mechanics and laborers shall rank pari passu on said twenty per cent. (See R.S.O.c. 126, s. 9, ss. 3.)

(2) Every wage earner shall be entitled to enforce a lien in respect of the contract not completely fulfilled. (See 56 Vict. c. 24, s. 5, ss. 2.)

(3) In case of the contract not having been completely fulfilled when the lien is claimed by wage earners, the percentage aforesaid shall be calculated on the work done or materials furnished by the contractor or sub-contractor by whom such wage-earners are employed. 56 Vict. c. 24, s. 5, ss. 1.

(4) Where the contractor or sub-contractor makes default in completing his contract the percentage aforesaid shall not, as against a wage earner claiming a lien under this Act, be applied to the completion of the contract or for any other purpose by the owner or contractor, nor to the payment of damages for the non-completion of the contract by the contractor or sub-contractor, nor in payment or satisfaction of any claim of any kind against the contractor or sub-contractor. (See 56 Vict. c. 24, s. 5, ss. 3.)

(5) Every device by any owner, contractor or sub-contractor, adopted to defeat the priority given to wage earners for their wages by this Act shall, as respects such wage earners, be null and void. 56 Vict. cap. 24, sec. 1.

(6) "Wages" shall mean money earned by a mechanic or laborer for work done, whether by the day or as piece work.

14. Nothing in this Act contained shall apply to make legal any payment made for the purpose of defeating or impairing a claim for a lien arising or existing under this Act and all such payments shall be taken to be null and void. (See R. S. O. c. 126, s. 9.)

15.—(1) During the continuance of a lien no portion of the materials affected thereby shall be removed to the prejudice of the lien, and any attempt at such removal may be restrained on application to the High Court, or to a judge or officer having power to try an action to realize a lien under this Act. R. S. O. c. 126, s. 15.

(2) The court, judge or officer to whom any such application is made, may make such order as to the costs of and incidental to the application and order as he deems just.

(3) When any material is actually brought upon any land to be used in connection with such land for any of the purposes enumerated in section 5 of this Act, the same shall not be subject to execution or other process to enforce any debt (other than for the purchase thereof) due by the person furnishing the same. (See R. S. O. c. 126, s. 31.)

16. A claim for lien applicable to the case may be registered in the registry office of the registry division or in the Land Titles office in which the land is situated, and shall state :

(a) The name and residence of the (person claiming the lien) and of the owner of the property to be charged ; or of the person whom the person claiming the lien, or his agent, believes to be the owner of the property to be charged) of the person for or whom and upon whose credit the work (or service) is done, or materials furnished or placed, and the time or period within which the same was, or was to be, done or furnished or placed.

(b) A short description of the work (or service) done or materials furnished or placed or to be furnished or placed.

(c) The sum claimed as due or to become due.

(d) The description of the land to be charged sufficient for the purpose of registration

(e) The date of expiry of the period of credit (if any) agreed by the lienholder for payment for his work (or service) or materials where credit has been given.

(2) The claim may be in one of the forms given in the schedule to this Act and shall be verified by the affidavit of the person claiming the lien or of his agent or assignee having a personal knowledge of the matters required to be verified, and the affidavit of the agent or assignee shall state that he has such knowledge. R. S. O. c. 126, s. 16.

(3) Where a lien is registered against the lands of a railway company it shall be sufficient description of the said lands to refer to the same as the lands of such railway company in the county where the claim arose as described and shown on the plan of the said railway registered under The Railway Act.

17. A claim for lien may include claims against any number of properties, and any number of persons claiming liens upon the same property, may unite therein, but where more than one lien is included in one claim each lien shall be verified by affidavit as provided in section 16 of this Act. (R. S. O. c. 126, s. 19.)

18.—(1) A substantial compliance with sections 16 and 17 of this Act shall only be required, and no lien shall be invalidated by reason of failure to comply with any of the requisites of sections 16 and 17 of this Act unless in the opinion of the court or judge or officer who has power to try an action under this Act, the owner, contractor or sub-contractor, mortgagee or other person, as the case may be, is prejudiced thereby, and then only to the extent to which he is thereby prejudiced.

(2) Nothing in this section contained shall be construed as dispensing with registration of the lien required by this Act.

19.—The registrar, upon payment of his fee, shall register the claim, so that the same may appear as an incumbrance against the land therein described. R. S. O. 1887, c. 126, s. 18, s.s. 1.

(2) The fee for registration shall be twenty-five cents. If several persons join in one claim, the registrar shall have a further fee of (ten) cents for every person after the first. 45 Vic. c. 15, s. 11.

3. The registrar shall not be bound to copy in any registry book any claim or affidavit, but he shall number each claim, and shall insert in the alphabetical and abstract indexes the like particulars as in other cases ; he may describe the nature of the instrument as "Mechanics' Lien" 45 Vic. c. 15, s. 11.

20. Whenever a claim is so registered, the person entitled to the lien shall be deemed a purchaser pro tanto, and within the provisions of The Registry Act, 1893, but except as herein otherwise provided, The Registry Act, 1893, shall not apply to any lien arising under this Act. R. S. O. 1887, c. 126, s. 19.

21.—(1) A claim for lien by a contractor or sub-contractor may be registered before or during the performance of the contract or within thirty days after the completion thereof.

(2) A claim for lien for materials may be registered before or during the furnishing or placing thereof or within thirty days after the furnishing or placing of the last material so furnished or placed.

(3) A claim for lien for services may be registered at any time during the performance of the service or within thirty days after the completion of the service.

(4) A claim for lien for work may be registered at any time during the work or within thirty days after the last day's work for which the lien is claimed. R. S. O. 126, s. 20 and sec. 31 in part.

22. Every lien which is not duly registered under the provisions of this Act shall absolutely cease to exist on the expiration of the time hereinbefore limited for the registration thereof unless in the mean time an action is commenced to realize the claim, or in which the claim may be realized under the provisions of this Act, and a certificate thereof issued in the manner required by section 52 of The Registry Act, 1893, is duly registered in the Registry Office of the Registry Division or the lands in respect of which the lien is claimed are situate. R. S. O. 1887, c. 126, s. 22.

23.—(1) Every lien which has been duly registered under the provisions of this Act shall absolutely cease to exist after the expiration of ninety days after the work or service has been completed or materials have been furnished or placed, or the expiry of the period of credit, where such period is mentioned, in the claim of lien registered, unless in the mean time an action is commenced to realize the claim under the provisions of this Act or an action is commenced in which the claim may be realized under the provisions of this Act, and a certificate thereof issued in the manner required by section 52 of The Registry Act, 1893, is duly registered in the Registry Office of the Registry Division or in the land titles office wherein the lands in respect of which the lien is claimed are situate. R. S. O. 1887, c. 126, s. 23.

(2) The registration of a lien shall cease to have any effect at the expiration of six months from the registration thereof, unless the lien shall be again registered within the said period, except, in the meantime, proceedings have been instituted to realize the claim and a certificate thereof has been duly registered in the proper registry or land titles office. 56 Vic., c. 24, s. 19.

24. If there is no period of credit, or if the date of the expiry of the period of

credit is not stated in the claim so registered, the lien shall cease to exist upon the expiration of ninety days after the work or service has been completed or materials furnished or placed unless in the meantime an action shall have been commenced and a certificate registered as required by section 23 of this Act, (R. S. O., c. 126, s. 24.)

25 In the event of the death of a lien-holder his right of lien shall pass to his personal representatives and the right of a lien-holder may be assigned by any instrument in writing. R. S. O., 1887, c. 126, s. 25.

26.—(1) A lien may be discharged by a receipt signed by the claimant, or his agent duly authorized in writing, acknowledging payment, and verified by affidavit and registered ; such receipt shall be numbered and entered by the Registrar like other instruments but need not be copied in any book, but the Registrar shall enter against the entry of the lien to which the discharge relates the word "discharged," and state the registration number of such discharge ; the fees shall be the same as for registering a claim of lien. R. S. O. c. 126, s. .6.

(2) Upon application the court or judge or other officer having power to try an action to realize a lien, may receive security or payment into court in lieu of the amount of the claim and may thereupon vacate the registration of the lien. R. S. O. c. 126, s. 30, ss. (7).

(3) The court or such judge or other officer may vacate the said registration upon any other ground. R. S. O., 1887, c. 126, s. 30, ss. 7 and 8.

(4) Where the certificate required by section 22 or section 23 of this Act has not been registered within the time limited, and an application is made to vacate the registration of a lien after the time for registration of the certificate required by section 22 or 23 of this Act, the applicant shall not be required to give notice of the application to the person claiming the lien, and the order vacating the lien may be made ex parte upon production of the certificate of the proper Registrar's certifying the facts entitling the applicant to such order.

(5) The taking of any security for, or the acceptance of any promissory note for, or the taking of any other acknowledgement of the claim, or the giving of time for the payment of the claim, or the taking of any proceedings for the recovery of the claim or the recovery of any personal judgment for the claim, shall not merge, waive, pay, satisfy, prejudice or destroy any lien created by this Act, unless the lien-holder agrees in writing that it shall have that effect ; provided, however, that a person who has extended the time for payment of any claim for which he has a lien under this Act to obtain the benefit of this sub-section shall commence an action to enforce such lien within the time limited by this Act, and register a certificate as required by sections 22 or 23 of this Act, but no further proceedings shall be taken in the action until the expiration of such extended time ; provided further that notwithstanding such extension of time, such person may, when an action is commenced by any other person to enforce a lien against the same property, prove and obtain payment of his claim in such action, as if no such extension had been given.

27. Any lien-holder may at any time demand of the owner, or his agent, the terms of the contract or agreement with the contractor for and in respect of which the work, services or materials is or are performed or furnished or placed, and if such owner or his said agent shall at the time of such demand neglect or refuse to inform the person making such demand, of the terms of such contract or agreement, and the amount due and unpaid upon such contract or agreement, or shall intentionally or knowingly, falsely state the terms of said contract or agreement, or the amount due or unpaid thereon, and if the person claiming the lien shall sustain loss by reason of such refusal or neglect or false statement, said owner shall be liable to him in an action therefor to the amount of such loss.

28. The court or judge, or other officer having power to try an action to realize a lien, may on a summary application at any time before or after any action is commenced for the enforcement of such lien, make an order for the owner or his agent to produce and allow any lien holder to inspect any such contract, and may make such an order as to the costs of such application and order as may be just.

29.—(1) The liens created by this act may be realized by actions in the High Court according to the ordinary procedure of that court, excepting where the same is varied by this Act.

(2) Without issuing a writ of summons, an action under this Act shall be commenced by filing in the proper office a statement of claim, verified by affidavit.

(3) The statement of claim shall be served within one month after it is filed, but a judge or other officer having power to try the action may extend the time for service thereof, and the time for delivering a statement of defence shall be the same as for entering an appearance in an action in the High Court.

(4) It shall not be necessary to make any lien holders parties defendant to the action, but all lien holders served with the notice of trial shall for all purposes be treated as if they were parties to the action.

30. Any number of lien-holders, claiming liens on the same property, may join in an action, and any action brought by a lien-holder shall be taken to be brought on behalf of all other lien-holders on the property in question. See R.S.O., c. 126, s. 30; 53 Vic. c. 37, s. 39.

31. An action to enforce a lien may be tried by the Master in Ordinary, a local master of the High Court, an official referee or a judge of the County Court, in any country or judicial district in which the lands are situate ; or by a judge of the High Court of Justice at any sittings of that court for the trial of actions.

32. The Master in Ordinary, the local masters, official referees, and the County Judges, shall have in addition to their ordinary powers, all the jurisdiction, powers and authority, of a Judge of the High Court of the Master in Ordinary, to try, and otherwise completely dispose of, an action to realize a lien, and all questions arising in such action, including the giving or refusing of the costs hereinafter provided.

33. (1) After the delivery of the statement of defence where the plaintiff's claim is disputed, or after the time for delivery of defence in all other cases where it is desired to try the action other than at the ordinary sittings of the High Court, either party may apply to a judge or other officer who has the power to try the action, to fix a day for the trial thereof, and the said judge, or other officer, shall give an appointment fixing the day and place of trial, and on the day fixed, or at such other day to which the trial may be adjourned, shall proceed to try the action, and all questions which arise therein, or which are necessary to be tried, to completely dispose of the action and to adjust the rights and liabilities of the persons appearing before him or upon whom the notice of trial has been served and, at the trial, shall take all accounts, make all inquiries and give all directions, and do all things necessary to try, and otherwise finally dispose of the action and of all matters, questions and accounts arising in the action or at the trial, and to adjust the rights and liabilities of and give all necessary relief to all parties to the action or who have been served with the notice of trial, and shall embody all the results in the judgment.

(2) The judge or officer who tries the action may order that the estate or interest charged with the lien may be sold, and when, by the judgment, a sale is directed of the estate or interest charged with the lien, the judge or officer who tries the action may direct the sale to take place at any time after judgment, allowing, however, a reasonable time for advertising such sale.

(3) The judge or officer who tries the action may also direct the sale of any materials and authorize the removal thereof. See R.S.O. 126, s. 30, s. s. 3 and 4.

(4) Any lien-holder, who has not proved his claim at the trial of any action to enforce a lien, on application to the judge, or officer who tried the action on such terms as to costs and otherwise as may be just, may be let in to prove his claim at any time before the amount realized in the action for the satisfaction of liens has been distributed, and when any such claim is proved and allowed the judge or officer shall amend the judgment so as to include such claim therein.

(5) When a sale is had, the Judge or officer with whose approbation the lands are sold shall make a report on sale and therein direct to whom the moneys in court shall be paid, and may add to the claim of the person conducting the sale his actual disbursements incurred in connection therewith, and where sufficient to satisfy the judgment and costs is not realized from the sale, he shall certify the amount of the deficiency and the names of the persons, with their amounts, who are entitled to recover the same, and the persons by the judgment adjudged to pay the same, and such persons shall be entitled to enforce the same by execution or otherwise as a judgment of the court.

(6) Any lien-holder for an amount not exceeding $100, or any lien-holder not a party to the action, may attend in person at the trial of an action to enforce a lien, and on any proceedings in such action, or may be represented thereat or thereon by a solicitor or by an agent who is not a solicitor.

34. The party obtaining an appointment fixing the day and place of trial shall, at least eight clear days before the day fixed for the trial, serve a notice of trial which may be in the form in the schedule to this Act, upon the solicitors for the defendants who appear by solicitors, and on all lien-holders known to him, who have registered their liens as required by this Act, and on all other persons having any charge or incumbrance, or claim on the said lands, who are not parties, or, who, being parties, appear personally in the said action, and such service shall be personal unless otherwise directed by the Judge or officer who is to try the case, who may, in lieu of personal service, direct in what manner the notice of trial may be served.

35. Where more than one action is brought to realize liens in respect of the same property, a judge or other officer having power to try such actions, may, on the application of any party to any one of such actions, or on the application of any other person interested, consolidate all such actions into one action, and may give the conduct of the consolidated action to any plaintiff to whom in his discretion he sees fit. (See 56 Vic. c. 24, s. 12.)

36. Any lien-holder entitled to the benefit of the action may apply for the carriage of the proceedings, and the judge or any other officer having power to try the action, may thereupon make such an order, giving such lien-holder the carriage of the proceedings, and such lien-holder shall for all purposes thereafter be the plaintiff in the action. See R.S.O. c. 126, s. 30, ss. 2, and 53 Vic. c. 37, s. 26.)

37. No fees in stamps or money shall be payable to any judge or other officer in any action brought to realize a lien under this act, nor on any filing, order, record or judgment, or other proceeding in such action, excepting that every person other than a wage earner shall, on filing his statement of claim where he is a plaintiff, or in proving his claim where he is not a party plaintiff, pay in stamps one dollar on every one hundred dollars, or fraction of one hundred dollars, of the amount of his claim up to one thousand dollars. (See 56 Vict., c. 24, s. 18.)

38. In all actions where the amount recovered by the judgment is $100 or less, the said judgment shall be final, binding, and without appeal, except that upon application within fourteen days after judgment is pronounced, to the judge or officer who tried the same, he may grant a new trial.

39. In all actions where the amount recovered by the judgment is more than $100 but not more than $200, any party affected thereby may appeal therefrom to a Divisional Court, whose judgment shall be final, binding, and no appeal shall lie therefrom.

40. In all other cases the same right to appeal shall exist as is given in actions tried without a jury in the High Court.

41. The costs of the action awarded in any action under this Act, by the judge or officer trying the action, to the plaintiffs and successful lien-holders shall not exceed in the aggregate an amount equal to twenty-five per cent. of the amount of the judgment besides actual disbursements, and shall be in addition to the amount of the judgment, and shall be apportioned and borne in such proportion as the judge or officer who tries the action may direct.

42. Where the costs are awarded against the plaintiff or other persons claiming the lien, such costs shall not exceed an amount in the aggregate equal to twenty-five per cent. of the claim of the plaintiff and other claimants, besides actual disbursements, and shall be apportioned and borne as the judge or said other officer may direct.

43. In case the least expensive course is not taken by a plaintiff under this Act the costs allowed to the solicitor shall in no case exceed what would have been incurred if the least expensive course had been taken. 56 Vic., c. 24, s. s. 15.

44. Where a lien is discharged or vacated under section 26 of this Act or when in an action judgment is given in favor of a lien in addition to the costs of action, the judge or said other officer may allow a reasonable amount for costs of drawing and registering a lien or for vacating the registration of the lien. R. S. O., 126, s. 30, s.s. 5 and 9.

45. Excepting in actions tried by a judge of the High Court the judge or other officer who tries the action shall where money has been paid into court and the time for payment out arrives, forward a requisition for cheques with a certified copy of his judgment, or when one is made of the report on sale, to the accountant of the Supreme Court of Judicature, who shall upon receiving said requisition and copy of the judgment or report make out and return to the said judge or officer cheques for the amounts payable to the persons specified in the requisition, and the said judge or officer on receipt of said cheques shall distribute them to the persons entitled.

46. No fees or stamps shall be payable on any cheques or proceedings to pay money into court or obtain money out of court, in respect of a claim of lien, but sufficient postage stamps to prepay a return letter shall be enclosed with every requisition for cheques.

47. All judgments in favor of lien-holders shall adjudge that the person or persons personally liable for the amount of the judgment, shall pay any deficiency which may remain after sale of the property adjudged to be sold, and whenever on a sale of any prope ty to realize a lien under this act sufficient to satisfy the judgment and costs is not realized therefrom, the deficiency may be recovered by execution against the property of such person or persons.

48. Whenever in an action brought under the provisions of this Act any claimant shall fail for any reason to establish a valid lien he may nevertheless recover therein a personal judgment against the party or parties to the action for such sum or sums as may appear to be due to him from him or them and which he might recover in an action in contract against such party or parties.

49. The forms in the schedule hereto, or forms similar thereto or to the like effect, may be adopted in all proceedings under this Act.

50. This act shall not apply to liens arising before the coming into force of this Act excepting that where no action has been commenced or proceeding instituted to realize a lien arising before the coming into force of this Act the procedure herein directed shall be adopted to realize the same.

51.—(1) Every mechanic or other person who has bestowed money or skill and materials upon any chattel or thing in the alteration and improvement in its properties or for the purpose of imparting an additional value to it so as thereby to be entitled to a lien upon such chattel or thing for the amount of value of the money or skill and materials bestowed, shall, while such lien exists, but not afterwards, in case the amount to which he is entitled remains unpaid for three months after the same ought to have been paid, have the right in addition to all other remedies provided by law, to sell by auction the chattel or thing in respect of which the lien exists, on giving one week's notice by advertisement in a newspaper published in the municipality in which the work was done, or in case there is no newspaper published in such municipality, then in a newspaper published nearest thereto, stating the name of the person indebted the amount of the debt, a description of the chattel or thing to be sold, the time and place of sale, and the name of the auctioneer, and leaving a like notice in writing at the last known place of residence (if any) of the owner, if he be a resident of such municipality.

(2) Such mechanic or other person shall apply the proceeds of the sale in payment of the amount due to him and the costs of advertising and sale, and shall upon application pay over any surplus to the person entitled thereto. 51 Vic., c. 27, s. 1.

52. Excepting in so far as is necessary to preserve the liens and rights, causes of action and defences thereto arising or existing thereunder before the coming into force of this Act, the following Acts and parts of Acts shall not apply after the coming into force of this Act, and are hereby repealed :—

Chapter 126 of the Revised Statues of Ontario, 1887, and all amendments thereto.

The Act passed in the 53rd year of Her Majesty's reign, chaptered 36 and all amendments thereto

The Act passed in the 56th year of Her Majesty's reign, chaptered 24 and all amendments thereto.

The Toronto School of Practical Science Engineering Society has elected the following officers for the ensuing year : President, C. F. King ; Vice-President, H. S. Carpenter ; Treasurer, A. G. Piper ; Corresponding Secretary, H. L. Vercoe ; Recording Secretary, H. R. Stovel ; Librarian, W. A. B. Hicks ; Fourth Year Representative, J. A. De Cew ; Third Year Representative, M. B. Weeks ; Second Year Representative, J. Shaw. C. MacBeth, J. A. Bow and T. J. Little were elected to "Varsity" Editorial Board.

The reconstruction of the new building for the Montreal Street Railway Company has been completed. The question of strength has been made paramount to all other considerations. The entire building is carried on steel columns, which rest in concrete and brick foundations laid in gravel, and this load represents 13-4 tons per square foot. Each floor, as well as the roof, is formed of steel girders and fifteen-inch hollow tile floor arches, covered with Portland cement, the whole being supported by steel columns, which in turn are protected by hollow terra cotta tile.

2. In registering such memorial, it is sufficient to mention, opposite the official number of the cadastre which describes the immoveable, if the cadastre be deposited, or opposite the title of the registered deed, if the cadastre be not yet deposited, the name of the claimant and the amount due at the time the memorial is filed.

3. The memorial shall be made out in duplicate, one copy of which shall remain in the archives of the registry office and the other be delivered to the creditor with the registrar's certificate thereon.

4. The creditor shall, within three days from the registration of the memorial, give a written notice to the proprietor of the immoveable, or to his agents, if he cannot be found."

4. The act 57 Victoria, chapter 46, and all other provisions of the Civil Code inconsistent with this act, are repealed.

MONTREAL SKETCH CLUB.

After much exertion and not a few discouragements, new efefforts were recently made to organize in this city a Sketch Club. A general meeting was called on Friday, March 20th, to discuss the advisibility of organizing, at which a large number of students were present. The evening was devoted to considering the requisites of a club of this character, and the work of organization completed. The architects very kindly tendered the use of their rooms to the Club, which offer was gratefully accepted. The Club has been very active since its organization, and it is certain that in a short time it will prove its utility. One Saturday afternoon an enjoyable visit was paid to the Chateau de Ramezay, now converted into an historical museum. The Club is formed for mutual help in matters of design, lectures and discussions. Several other methods of effecting this object are to be employed. One night a week (Friday) is set apart as Club night. Monthly competitions are to be held, the work submitted at these competitions to be criticised by a jury of architects. The jury is formed of three officers, and forms the Executive Committee.

During the summer months the Club will make sketching tours in the surrounding country.

The Club has my best wishes for a long and prosperous career.

P. Q. A. A. STUDENTS' EXAMINATIONS.

The semi-annual examinations of the Province of Quebec Association of Architects were held in the office of Mr. F. X. Berlinquet, St. John street, Quebec, on the 20th, 30th, and 31st of January last. Four candidates presented themselves and have passed with success the final examination, viz., Messrs. J. E. Payette, J. Forget Despatie, and P. A. R. Labelle. The only candidate for matriculation examinations was Mr. P. Levesque, of Quebec. The examiners were Messrs. Charles Baillarge, F. X. Berlinquet, and F. X. Peachy.

ROYAL ACADEMY EXHIBITION.

Those who had the advantage of visiting the exhibition of the Royal Canadian Academy held in the Art Association building, Philips Square, must have remarked the progress achieved by the painters. Every year the outlook seems more promising, and shows a marked advance in the works exhibited. There are to be seen some very fine landscapes, pleasing and altogether successful water color sketches, particularly of Rocky Mountain scenery. The lady artists have done very good work. Some very fine pieces of decorative work can also be seen. The architectural section is represented by drawings by Mr. A. T. Taylor, R. C. A. The principal exhibitors are: Robert Harris, A. R. C. A.; Mrs. Peterson; Homer Watson, R. C. A.; William Brymer, R. C. A.; James L. Graham, A. R. C. A.; J. Forthard, R. C. A.; Miss Sarah Holden, Miss Ford, and others.

The architectural firm of Edwards & Webster, Toronto, has been dissolved. Mr. H. J. Webster has opened an office in the west wing of the Confederation Life Building.

The death is announced of Mr. C. J. King, a prominent contractor of Victoria, B. C., in his 55th year.

Mr. Thomas Askwith, of the firm of Askwith & Neville, contractors, Ottawa, was seriously injured recently by an explosion of gas from the furnace.

Black Enamel for Wood.—The following recipe will prove of value to cabinet makers: Prime the wood with linseed oil, turpentine and white lead; then give it two or three coats of black, mixed with copal varnish and turpentine; rub it down dry with pumice stone and water; finally, varnish with copal. Again rub down, and polish with oil and rotten-stone to obtain perfect smoothness.

NOTES OF AN ARCHITECTURAL TOUR IN ENGLAND AND FRANCE.*

By W. A. Langton.

I propose to speak only of the new work that I saw. I was brought first into contact with churches. I did not see many, but thought from what I saw that the English architect does not trouble himself too much with the problem of providing for the congregation a clear floor space and an unobstructed view of the chancel and pulpit. The objection to columns has been exaggerated and they have, on the other hand, great value as a means of marking proportion and obtaining effects of space; but there is no retreat from the modern conditions which make that the perfect plan which gives the greatest proportional space to seats and gives each seat an unobstructed view of at least the pulpit. With this in view it is impossible to give more than a qualified admiration to many beautiful modern churches which derive the best part of their beauty from an arcaded plan which is not made necessary by the extent of their area. But I was glad to find churches which show that the arcade has still a use. The best example of this that I met was the late J. D. Sedding's Holy Trinity church, at Sloane Square, London. Here there is a wide nave and narrow aisles. The congregation sit between the nave piers, all in full view of the chancel, and the aisles are only used for passages. The entire width from aisle wall to aisle wall is 64 feet; the distance between the nave piers is only 38 feet. If there had been no arcade the cost of a roof to span 64 feet and of a wall to carry it would have been much greater than that of either the roofs or walling which are sufficient for the present arrangement—a nave 38 feet wide with 8 foot aisles—for after a certain span of roof is exceeded, the cost involved in its making, raising and support must increase in a rapid proportion for each additional foot.

This plan of Sedding's is satisfactory in its effect not only because of the division into the nave and aisles, but because of the manner in which they are divided. The nave is important, the aisles only passages. The character of each part is well marked and the church gains in dignity and in picturesqueness too. It is incidentally interesting to reflect that this is true traditionalism, and might have been attained at once if the gothic revivalists had studied the purpose of the ancient builders as well as their results; for the aisles are understood to have been intended by the early builders not for the congregation but for the passage of processions and if the revivalists had recognized the poetry of plan they would not have felt bound by the ancient proportion between nave and aisles but would have adapted them, as has been done in this church, to our manner of worship which makes the placing of the congregation all important, and the only procession in the aisles is their procession to their seats.

My principal object in going to London was to see the new work which, as represented in the English journals, appears to be so beautiful. Viewed in situ it was, on the whole, disappointing. The work is of the highest quality, refined, scholarly and exact, but the result on the street is small. The general characteristic is a small scale with a great deal of ornament. The scale reminds one of a Dutch or Flemish town; and there it would be seen to advantage, but it cannot hold its own against London. As for the ornament no detail which is intended to give pleasure in itself is in place in London. An angel with his mouth full of soot can give no pleasure or ever seem in place. The only kind of carved ornament which is none the worse for black is the meaningless renaissance forms such as swags. No one thinks of the flowers of which they are made up; the line is everything and this is emphasized by the black and white marking of London. In fact the proper street effect in London seems to be exemplified in the buildings of Wren and his followers, which are generally built of grey stone and broadly handled. The London smoke can do them no harm but rather enhances their effect. Indeed black and white is the proper London effect. It is the effect of Wren's churches both inside and outside and to the stranger in London is charming. The Londoner, no doubt, looks upon it as commonplace and barren and wants to import effects of colour.

I cannot see why we should love the renaissance. It is hostile to most of the objects for which we build. Yet it does seem to lend itself especially to the breadth which is so important for street building. The Banqueting Hall of Whitehall for all its elegance would hold its own amongst any neighbours, and commands our constant admiration although it is impossible to consider its principal feature—the detached column with both cornice

*Abstract of a Paper read before the Ontario Association of Architects.

and balustrade breaking round it—anything but a foolish invention.

The greatest success among the recent buildings in the city—Mr. Belcher's Institute of Chartered Accountants—is good English renaissance. Its beauty is in its scale even in the carving, and though now beautiful in its whiteness it should be still beautiful when blackened.

The blackening of a cut stone building is not by any means uniform but is subject to accidents from the varying exposure of the surfaces to wet and currents of air. The result is, in the upper parts of the buildings, an arrangement of scoured white on exposed surfaces and black deposit in quirks and quiet corners that could not be bettered if done intentionally. The effect of columns is peculiarly favored by this process, and all bold work is favoured, but the mean is only made meaner. St. Paul's seems to have gained rather than lost beauty from a couple of centuries of soot. There is a capriciousness about the lines of scouring and marking that suggest eddies caused by external influence and suggest a danger in the tall buildings that are growing up round the church yard. An alteration in the course of the prevailing eddies so as to deposit black on what is now white would spoil perhaps permanently the beauty of the present arrangement.

After coming to the conclusion I have stated about the renaissance I went to Paris and was pleased to believe I had found there a street architecture which had extracted from the renaissance simple and reasonable elements which produced its good qualities without its follies. In this respect the ordinary street architecture is a better example than higher flights of individual ambition. There is little in it but good proportion and the detail is applied so as to help this rather than be a source of interest in itself. Each opening is surrounded by an architrave and there are string courses and a cornice. All of these are built as blocks and planed afterwards, for they have at Paris the supreme advantage of an easily worked and yet durable stone. As a consequence there is also much carving, but used generally in a temperate manner, as finish rather than adornment. The stone is white and remains white, for though there is too much smoke hanging over Paris to allow of its being seen well from adjacent heights, the smoke does not seem to obscure the sunshine in the city or blacken the buildings.

The wall surfaces of buildings of an inferior class, if not those of the better class, are usually I fancy rough brick plastered and the stone is used only to trim openings, but there is no noticeable difference in the appearance and the total effect of these continuous white buildings is very beautiful. When summer comes and the trees on the boulevards are green, the streets must be many degrees more beautiful than when I saw them.

There was a tendency in the newer quarters of Paris, and in the suburbs, to abandon the simplicity of this old fashioned building and seek more bizarre effects but though the individual perhaps appears here, there is no departure from the accepted type. The fact is that France has a living style of architecture. The manner of building is traditional and the results conform to type.

I made a note of the construction of a commonplace house which I saw in the process of erection in a small country town and which I considered to be a typical example. The house was of two storeys below the roof. The external walls were of rough stonework for plastering. The openings were trimmed with stone in the front of the building and with brick at the back, set out so as to project beyond the plaster line. The space between the front and rear walls was 32 feet. It was sub-divided by a partition wall of brick which was 16 inches in the cellar, but for the two storeys above only 4 inches. It carried the ends of 5½" iron beams running from the front and rear walls which carried a floor of hollow bricks. The roof was not yet on this building, but would probably be of tiles fastened to wooden laths.

Though the style is traditional the materials are modern. Indeed it seemed to me that one of the evidences of the living character of French architecture is the straightforward way in which they use iron. It is commonly used to span wide openings, sometimes with an arch over it, sometimes it acts as support for a stone lintel. But I was most impressed with the excellent spirit of the French, by the way they expose iron in roofs and ceilings where it must look well. Sometimes they come out of this well, sometimes the result is crude, but it at any rate appeals to one as a spirited effort.

Whatever view may be taken of either the form of the French houses or the method of building them, (and for my own part I have always admired the plastered wall with stone trimmings) there can be no question I think that the country which has a traditional and recognized practice is fortunate; for not only are building operations simplified, and the expense of them, I should think, both less and more easily calculated, but the effect of the national art is greater.

In respect of the question of style I do not feel much more determined than before this tour, but one strong impression I have received, which is that a town is most interesting when its buildings are similar in character, whatever the style may be, and that any building which differs unnecessarily from the accepted type is an unpleasing interruption and must be very good indeed in order to be acceptable on its own account. When one comes to a place like the new part of New York, where there is as much variety of architecture in a square mile as there is in the whole of France, all architectural character is gone. The technical merit is of the highest order, but the effect of the whole upon the imagination is no greater than that of a museum of art.

As we are in the same position as architects in the United States, that is to say without tradition or governing idea, this is perhaps not a comforting impression to have received, but it is at least confirmatory of views which have been expressed here before and are, I believe, the architectural faith of many of us:—That attention to our own problems is both the surest safeguard against going wrong in our taste, and the surest way of giving to our work the expression of character to which style is always subordinate, and which is the essential characteristic of all good work in all styles.

ILLUSTRATIONS.

DESIGN FOR A SUMMER HOTEL.—G. A. MONETTE, ARCHITECT, MONTREAL.

SKETCHING COMPETITIONS IN THE SCHOOL OF FINE ARTS, PARIS.—SKETCH BY J. A. MARCHAND.

RESIDENCE ON MADISON AVENUE, TORONTO.—HENRY SIMPSON, ARCHITECT.

BUSINESS PREMISES AT GANANOQUE, ONT. C. J. GIBSON, ARCHITECT.

RESIDENCE OF W. M. KNOWLES, WESTMOUNT, MONTREAL.—R. FINDLAY, ARCHITECT.

This building recently erected occupies a magnificent site upon the mountain slope. In the arrangement of plan advantage has been taken of the extensive view of the city, river, rapids and lake, and every effort made to secure comfort and convenience combined with all the advantages of this commanding position. The superstructure is built of pressed brick with sandstone trimmings and half-timbered work. A large staircase-hall forms the central feature of the house, from which the principal rooms are reached; and the interior has been handsomely finished throughout in hardwood. The lighting, heating and sanitary appliances and fittings are first-class in every respect.

Erratum.—In connection with the illustration of the proposed East End C. P. R. Depot, at Montreal, published in the Architect and Builder for March, the name of Mr. Geo. B. Post, of New York, was given as the architect of the building. This is incorrect. The architect is Mr. Bruce Price, of New York.

Note.—The following description of the design for a town hall, by Messrs. Edward Swales and W. Watkin, should have accompanied the illustration published in the Architect and Builder for March, but was inadvertently omitted: "The design for a town hall for a provincial town was recently submitted in public competition. The object aimed at was symmetry of plan and elevation, with simple treatment. The four departments provided are grouped round a central public hall with their inquiry offices, and are provided with private corridors, exits and conveniences, each department being distinct in itself. The main staircase immediately faces the entrance. The central feature, the large hall on the first floor to hold 500 (gallery included), is lighted from both sides, the buildings at the back being kept low, and is flanked by staircases treated as low towers. The council chamber is placed at the back, on the quiet side, away from the main street. Committee rooms, Magistrate's room, and retiring rooms have all private corridors and approaches. Caretaker and offices are provided on the second floor. Lifts to all floors. Storage for chairs from the hall. Heating and lighting is provided in the basement.

MR. JOHN ALDRIDGE.

PRESIDENT TORONTO BUILDERS' EXCHANGE.

THE gentleman of whom the accompanying portrait is a good likeness is Mr. John Aldridge, president of the Toronto Builders' Exchange and a prominet builder of the city. He is a native of Scotland, having been born at Brockenhurst, County of Hampshire, in 1851. At an early age he was apprenticed to the building trade with his father who carried on an extensive business. In 1871, when only 20 years old, he came to Toronto. At the commencement of the agitation that preceded the nine-hour movement in 1872 he removed to Peterboro'. At this time the old wooden town, which was burned down, was being reconstructed as a brick town, and contractors found plenty of employment. In partnership with his brother he erected many of the buildings which exist to-day in that town. In 1878 he returned to Toronto, where he has since resided, and for the greater part of that period has been engaged in building. Among other buildings erected by him may be mentioned the following: The Jesse Ketchum school; the block at the corner of Yonge and Gloucester streets;

MR. JOHN ALDRIDGE.
President Toronto Builders' Exchange.

James Robertson & Co.'s factory, King street west; the Crompton Corset Co.'s factory; the Nasmith building on King street, and the building lately occupied by the Empire Printing Company.

Mr. Aldridge was one of those who felt the necessity of a material change in the old Federated Association of Builders and Contractors, and advocated the formation of an association on more modern lines and in keeping with similar institutions in the United States. The ultimate result was the formation of the Builders' Exchange, with its working sections. Mr. Aldridge was elected a director on the Board of the Exchange at its organization, and has filled the position continuously ever since until last January, when he was elected to the office of President. He has always taken a deep interest in the success of the Exchange, and well deserves the honor which has been conferred upon him by its members.

Mr. Aldridge was one of the promoters of the organization of the Trades and Labor Council, in which society his executive ability was also recognized by his election as chief officer.

MANUFACTURES AND MATERIALS

READY-MADE MORTAR.

IT has long been the custom in many European cities, particularly in Germany, for builders to purchase their mortar ready-made from persons exclusively engaged in the manufacture of the material, instead of making it for themselves on the site of the building, as is the custom in Canada. Of late the European method has come into use in some of the larger American cities, and has been found to be more satisfactory than the old plan.

The writer had a conversation recently with a well-known contractor of Toronto, who proposes to try the experiment of manufacturing and supplying mortar to the builders of that city. It is beyond question that the material manufactured in this way should be superior in quality to that made under the present system, without proper facilities and by inexperienced workmen.

The present method is necessarily expensive and much of a nuisance to the builder and the public. No doubt builders would be glad enough to be rid of it if a more satisfactory one were presented to them. The only apparent obstacle in the way of the success of this new manufacturing venture is the inactivity in building enterprise prevailing at the present time, but which it is hoped will soon pass away.

The Prismatic Glass Co., of Toronto, has increased its capital stock to $25,000.

It is said that the Williams' stone quarry near Stonewall, Man., will be operated this summer on an extensive scale.

Mr. John Harrison, of Owen Sound, Ont., has commenced the manufacture of mantels for the decoration of fireplaces.

Granite is now being quarried in Shelburne county, N. S., for export to Scotland. Formerly granite was imported from Scotland for construction works in that province.

Messrs. Tayte, Meating & Co., of St. George, N. B., are supplying 20,000 feet of New Brunswick red granite for the construction of the Museum of Natural History at Manhattan Square, New York City. The granite will be shipped to New York by schooner.

A company is being formed at Ottawa, Ont., with a capital of $100,000, for the establishment of a manufactory of wood mantels and fancy woodwork. Among the promoters are Messrs. H. N. Bate, J. C. Brennan, C. A. Douglas, D. O'Connor, A. McKinnon, Sproule, Dowsley, and others.

The Whitton Granite Quarry Company, with a capital of $50,000, has been incorporated to deal in granite, stone and other building materials. The promoters are Joseph Bolduc, and G. H. Lacourciere, of St. Victor de Tring; Rufus H. Pope, of Cookshire; L. I. Frechette, of St. Ferdinand d'Halifax; Wilfred Trudeau, of Fall River, and D. Alfred Roy, of New Bedford, all of the province of Quebec.

There are about sixty three-cement works in the whole of Germany. The Rhine is the principal centre for this manufacture, but in the neighborhood of Hamburg there are three or four in operation for the production of the article. The annual production of Germany amounts to nearly 11,000,000 barrels. The largest customers for this article of trans-Atlantic countries are the United States, Brazil, Chile and Venezuela. The exportation to Great Britain and British possessions is comparatively small. The following table gives approximately the quantity and value exported to America: United States, 1,386,872 cwt., £168,000; Brazil, 449,340 cwt., £40,200; Chile, 131,000 cwt., £13,000; Venezuela, 103,000 cwt., £9,800.

We have received from Messrs. Copp Clark & Co., the publishers' Canadian agents, a copy of a book entitled "Electric Wiring," by Mr. Russell Robb, published by Messrs. McMillan & Co., New York. This book is designed for the use of architects, underwriters and the owners of buildings. Considerable space has been given to the National Code of Rules for electric wiring, reasons being given for each rule, together with explanations of the meanings of the technical terms and phrases used. The book appears to be well suited for its purpose and will doubtless be found of practical benefit to the classes in whose interests it has been compiled.

CANADIAN ARCHITECT AND BUILDER.

VOL. IX.—NO. 5. MAY, 1896 PRICE 20 CENTS $2.00 PER YEAR.

—THE—

CANADIAN ARCHITECT AND BUILDER,

A Monthly Journal of Modern Constructive Methods,

(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD).

PUBLISHED ON THE THIRD THURSDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS; AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

C. H. MORTIMER, Publisher,

Confederation Life Building, - TORONTO, CANADA.

Telephone 2362.

Branch Office: NEW YORK LIFE INSURANCE BUILDING, MONTREAL.

Bell Telephone 2299.

SUBSCRIPTIONS.

The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.

Prices for advertisements sent promptly on application. Orders for advertisements should reach the office of publication not later than the 12th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of technical value to the persons in whose interest this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publisher of any irregularity in delivery of paper.

Students' and Draughtsmen's Competition.

WE desire to call special attention to the announcement appearing in the Students' Department of this number of a competition for students and draughtsmen. The subject—a cover design for the next New Year Number of the CANADIAN ARCHITECT AND BUILDER—is one which affords ample scope for the display of artistic skill. It is hoped, therefore, that the competition will be keenly contested, and that a satisfactory result will be achieved.

Canadian Country Architecture.

THE past few years have witnessed a most decided and marked change in the class of dwellings erected in Canada. Many new and elegant buildings scattered throughout the country, particularly in Western Ontario, have been characterized by a better construction, a finer finish, and the exercise of greater care in regard to detail. Pine is rapidly giving place to black birch, cherry, ash, oak and maple. It is quite a common sight now to see a pretentious farm house faced with pressed bricks, having generous windows with plate glass, and with painted glass in hall windows, hardwood doors built up on a pine or basswood core, ornamental stairs and handrailing, and alternate strips of dark birch and light maple floors. We notice these improvements in materials and good taste over old methods, with a great deal of pride and satisfaction, for it denotes a measure of substantial prosperity that tells of the progress the whole country is making.

Hardwood Finish.

THERE is no part in the whole construction of a dwelling where the amount of money expended counts for so much as in the woodwork, especially that part of it that shows in the hallway and drawing room, and where possible, it is always in the interest of the builder to finish these parts in hardwood. A hardwood trim creates an instant impression of something substantial, while the expense is not greatly increased, for the quantity of lumber used in a hallway and drawing room of a country house is really small, and the extra labor involved in working hardwood is not by any means great. A few dollars at the most, will be all that will be required to cover the expense, the style of work being the same as in pine. The wide-awake contractor must be aware that country people have been seized with the onward march of progress, and he will bend his energies accordingly and be up to the times in arming himself with a knowledge of all new styles of

Students' and Draughtsmen's Competition.

WE desire to call special attention to the announcement appearing in the Students' Department of this number of a competition for students and draughtsmen. The subject a cover design for the next New Year Number of the CANADIAN ARCHITECT AND BUILDER—is one which affords ample scope for the display of artistic skill. It is hoped, therefore, that the competition will be keenly contested, and that a satisfactory result will be achieved.

Canadian Country Architecture.

THE past few years have witnessed a most decided and marked change in the class of dwellings erected in Canada. Many new and elegant buildings scattered throughout the country, particularly in Western Ontario, have been characterized by a better construction, a finer finish, and the exercise of greater care in regard to detail. Pine is rapidly giving place to black birch, cherry, ash, oak and maple. It is quite a common sight now to see a pretentious farm house faced with pressed bricks, having generous windows with plate glass, and with painted glass in hall windows, hardwood doors built up on a pine or basswood core, ornamental stairs and handrailing, and alternate strips of dark birch and light maple floors. We notice these improvements in materials and good taste over old methods, with a great deal of pride and satisfaction, for it denotes a measure of substantial prosperity that tells of the progress the whole country is making.

Hardwood Finish.

THERE is no part in the whole construction of a dwelling where the amount of money expended counts for so much as in the woodwork, especially that part of it that shows in the hallway and drawing room, and where possible, it is always in the interest of the builder to finish these parts in hardwood. A hardwood trim creates an instant impression of something substantial, while the expense is not greatly increased, for the quantity of lumber used in a hallway and drawing room of a country house is really small, and the extra labor involved in working hardwood is not by any means great. A few dollars at the most, will be all that will be required to cover the expense, the style of work being the same as in pine. The wide-awake contractor must be aware that country people have been seized with the onward march of progress, and he will bend his energies accordingly and be up to the times in arming himself with a knowledge of all new styles of

work and methods of performance. If he fail to do this some more progressive man will soon be in his neighborhood quietly but surely taking away his trade. In these days of active competition a man to be successful must keep abreast of the times, for the law of evolution obtains in the building trades as well as in other matters, and it is only "the fittest that survive."

A Generous Offer.

THE Maharajah of Jeypore, India, has offered to supply free of charge to public institutions for the education of the young, six portfolios, containing 374 plates 15 x 22 inches in size, some in color, illustrating the most beautiful architectural work of India. The only expense will be the cost of packing and carrying charges. These portfolios may be obtained through Messrs. W. Griggs & Sons, Elm House, Hanover Street, Rye Lane, Peckham, London. Our Canadian educational institutions should lose no time in making application for these interesting illustrations.

The Utilization of Convict Labor.

CANADA'S expenditures on public works have probably been larger than those of any other country of equal population and resources. These expenditures have been made for the purpose of promoting immigration and assisting the country's development. The latter object has been realized in a more satisfactory degree than the former. The government should now turn its special thought and attention to devising means of increasing by immigration the population of the country. There are yet a number of public works, the carrying out of which would tend to assist our national progress, but which cannot, at the present stage of our history, be paid for out of the public exchequer. Why should not the labor of the inmates of our prisons, who are now being supported at the public expense, be utilized for the construction of such public improvements? If the financial resources of the country forbid that these improvements be undertaken in the ordinary way, is it not advisable that they should be carried out by this only available method? No injury would be done to free labor, and the country would derive some return for the large sums of public money which are annually expended for the support of the criminal classes.

Advantages of Building in Summer.

BUILDING in the country is now well advanced, and in many of our towns and villages, work that was commenced before the cold weather departed, is drawing rapidly towards completion. Country contractors generally find a lull in the building trades about midsummer, and often owners, who intend building, delay giving out their work, so that out-door operations have to be done when the weather is in an unsuitable condition. This is a factor, seldom taken into consideration in the summer, which often proves a matter of serious loss to the contractor, who should try and urge those having work to give out, to let their contracts as early in the summer as possible. Generally work taken during the winter previous to execution, is not the most profitable, as frequently the necessities of individual workmen compel them to cut prices down to almost starvation point, and as a rule, before the work is completed both contractor and owner become disgusted with the job; then comes a series of dishonest strategems by the workman on the one hand, to beat the owner; and a period of dissatisfaction and grumble by the owner when he discovers the knavery of his contractor. Summer jobs always pay best, and are more certain to give satisfaction all round.

If work be taken in the fall of the year to be completed the summer following, the chances are that both contractor and owner will be better served than if let under any other conditions. This would give the contractor ample time to digest his plans and to decide on the best and speediest methods of going about the work, and the owner would be better served, inasmuch as all his joiner's work would be—if the contractor does his duty—better seasoned, and in a much better condition to "stand" than if hurried from the factory to the building and put in place at once. The tendency in all our smaller towns is to "rush matters to completion," a tendency which acts injuriously to the whole building interests, and everyone engaged in these interests should set their faces against it. A good building, like a good tree, can only be the result of time naturally dispensed.

Safe Scaffolding.

As the tendency of the law is to make the contractor responsible for accidents to workmen caused by defective or improper scaffolding, it should be one of the chief objects of the foreman to see that every piece of scaffolding is sound, strong and sufficient. Many a limb has been broken and many a life lost because of the use of rotten or imperfect materials, or because enough nails have not been used in making the scaffold. Every contractor should have in stock a good scaffolding plant suitable for all work he may be called upon to perform. The English method of using good stout poles instead of sawn scantlings, is to be commended, as being safer and stronger, as the fibres of the grain are continuous throughout the whole length of the pole, whereas, in scantling, cross grain and knots render them liable to snap asunder at every sudden shock or strain. In scaffolding, when round poles are used, the putlogs or cross pieces are generally lashed to the poles with ropes—sometimes with chains—and this does away with the necessity of using nails to secure the brackets, and leaves the scaffolding undamaged when the work is completed. Taken all in all this manner of scaffolding, apart from being the safest, is, in the end, much more economical than the old slovenly way of nailing.

Tamarack or spruce poles are easily obtainable in Canada, and when once prepared and seasoned, if properly cared for, will last a lifetime and be as strong in the end as when first used. Putlogs should be made of straight grained rock elm, oak or rim ash. By using either of these woods, the dimensions may be small—not more than 3″ × 5″, and six feet will be found long enough to have them for most purposes. The ropes used for lashing should not be more than ¾ of an inch diam. and should be laid away in a dry situation when not in use. If the building is of wood that requires scaffolding, an ordinary right-angled bracket with braces nailed on each side, may be used instead of hardwood putlogs. The stuff from which these braces are made should be for the top and back, about 2″ × 5″, and the braces nailed on the sides at an angle of 45° should be of good sound stuff—pine—1″ × 5″. The space between these braces is where the sustaining pole is inserted when the bracket is in use. The height of the scaffold is regulated by moving the foot of the pole. To raise it higher the pole is moved closer to the wall, to lower it the foot of the pole is moved further away from the building. The difference between the lowest and highest point the bracket can reach, is limited by the length of the pole.

BUILDING TRADE DISSENSIONS.

BUILDING operations in Toronto have been affected during the past fortnight by a disagreement between employers and employees with respect to wages. Efforts were made by the Builders' Exchange, as well as the various building trades unions, to arrive at an agreement by which the season's operations would be carried on in harmony, and with the majority of trades this was effected. The agreement with the stonecutters has been renewed at the same rate of wages per hour as last year, while the stonemasons and bricklayers have signed an agreement at a considerable reduction. The Bricklayers' Union held out strongly against reduction but finally recognized the necessity of acceding to the proposition made by the master builders.

The Builders' Laborers' Union, however, notwithstanding the fact that agreements had been signed by the other branches at lower figures than last year, would not even accept the same rate as last year, which the builders were willing to pay, but apparently without considering existing conditions, demanded an increase of three cents per hour.

The refusal of the master builders to grant the request resulted in a strike being declared, which is still in progress. Several conferences between the parties to the disagreement have been held to endeavor to effect a settlement, but without success.

We are convinced that the strike has been brought on without proper consideration of the conditions in the building trades. It is admitted that building operations in Toronto during the present year are not likely to exceed those of last year, while many hold the view that their extent will be much less. The time, therefore, is not opportune for such a strike. The labor market is glutted, work scarce, and competition extremely keen.

Four years ago, the Trades and Labour Council, of which the Laborers' Union is a part, were successful in having a by-law passed by the City Council fixing the wages to be paid to laborers at 15 cents per hour as the least upon which a family could be maintained. At that time the purchasing power of a dollar was about one-half what it is to-day, consequently the workman who receives that amount to-day is in a much better position than he then was.

But probably the strongest proof of the unwise action of the laborers is found in the fact that the bricklayers and masons, who are skilled mechanics, and are compelled to spend several years in learning their trade, have considered it to their advantage to accept a lower rate of wages than last year. It is further claimed that few carpenters in Toronto receive a higher wage than is asked for by the laborers.

The master builders recognize the fact that it is not to their own interest to pay low wages, but in the face of the existing depression in the building trades the standard of wages is as high as can reasonably be demanded.

Mr. W. A. White, contractor, of Lindsay, Ont., was recently seriously injured by a safe falling upon him.

CORRESPONDENCE.

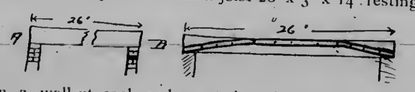
[Letters are invited for this department on subjects relating to the building interests. To secure insertion, all communications must be accompanied by the name and address of the author, not necessarily for publication. The publisher will not assume responsibility for the opinions of correspondents.]

A PROBLEM IN CONSTRUCTION.

KINGSTON, ONT., April 20, 1896.

To the Editor of the CANADIAN ARCHITECT AND BUILDER.

SIR,—Will you please answer the following question and give the figures to show the difference in carrying power, or rather the resistance to bending stress of the two beams of pine. Given a joist 26′ x 3″ x 14″ resting



on a wall at each end as at A and another of same dimensions as at B but having pieces of 1″ x 5″ pine, nailed on as shown, does the addition of these pieces stiffen the joist, and how much?

Yours truly,

JOHN H. BIRKETT.

ANSWER.—The safe load for a 3″ x 14″ white pine beam having a clear span of 24′, is 2,940 lbs. The 1″ x 5″ pieces, if thoroughly nailed to the beam or joist, would help to stiffen the same against sagging, but that would not materially strengthen the beam. It is impossible to secure the rider firm to the main beam when the span is so great and the depth so little, that the whole will act together as one piece. The resultant strain is very great and the side pieces would slip upon the main beam in response to any weight thrown upon them. There is also the shrinkage in the timber to be taken into consideration.

THE O. A. A.

To the Editor of the CANADIAN ARCHITECT AND BUILDER.

SIR,—As the proposed amendment to the Ontario Architects' Act has been withdrawn for the present, would it not be an opportune time for a discussion in your columns of the best means by which the Association might be strengthened? The more really active members the Association contains and the more good work can be done by it in raising the standard of architecture in our province, the more easily will the much desired legislation be obtained in the future.

The suggestion to form local chapters, which was made at one of the annual meetings, seems a good one. As it is now the members meet but once a year, while by more frequent gatherings of a less formal nature, much good fellowship might be promoted and much benefit be received by those attending. In this connection mention might be made of the meetings held by the English architectural societies, the reports of which in the English papers show the lively interest taken in them, not only by the members, but also by the professional journals, these reports forming no mean item in the contents of each number.

As Toronto is the headquarters of the Association and contains the largest proportion of its members, the initiative in the formation of such local chapters might well be taken here.

To carry out the proposal, convenient down town club rooms should be obtained. If these were comfortably furnished and provided with the leading technical journals, etc., they would soon become a pleasant meeting place for the architects. During the winter months lectures and occasional social gatherings could be arranged for the members, while for the students' section special classes and sketch competitions could be provided. By this means the social as well as the educational advantages of the Association would be greatly increased, and by keeping the daily papers informed of all meetings, the Association would become better known, and would be practically a necessity to all architects.

If these club rooms were obtained it should be arranged that the Registrar have his office and the library of the Association in connection, and all non-resident members should be made welcome to the use of the rooms, when in town. Of course the expense attached to such an undertaking would be borne by the local members. The way things are at present many Toronto architects support not only the O. A. A., but also the Guild and Sketch Club, which, of course, seems a needlessly heavy expense. If the two latter were in some way merged into the O. A. A., surely it would add to the power of the latter. It is surely not impossible to make the O. A. A. cover the entire ground of the three, and would most probably induce a better feeling and a stronger interest among those architects who are at present only half-hearted in their assistance to the O. A. A. in reaching the goal it is striving to attain.

Trusting that these views may meet with approval, and that some action may be taken accordingly, I am, dear sir,

Yours very truly,

A TORONTO MEMBER.

Toronto, May 1st, 1896.

DEFECTS OF ASPHALT PAVEMENTS.

THE doubts expressed in these columns last year concerning the merits of asphalt as a paving material on streets traversed by street car tracks, have proven to be well founded. The disappearance of ice and snow from the principal business thoroughfares of Toronto, viz., Yonge, King and Queen streets, has revealed the fact that between and on either side of the street car tracks, the asphalt has broken away in large patches from the concrete foundation, leaving the roadway full of great holes, unsightly to look upon and highly dangerous to traffic.

These pavements were laid four years ago at a cost of $2.80 per square yard, and in the belief that in them the city was securing a truly permanent pavement, the foundation of which would endure for about thirty years and the asphalt surface for about half that period. It is greatly disappointing to find that these expectations are not to be realized in any satisfactory degree, and that the recent large expenditures on pavements must be supplemented almost immediately.

It is true that the contractors are bound to keep the pavements in repair for five years, but a year hence that period will have expired, and then the cost of maintenance will fall upon the city. Soon after the city is called upon to assume the responsibility for keeping these pavements in repair it will probably be found necessary to renew entirely the asphalt surface. The cost of doing so will amount to about $1.50 per square yard, or above half the total original cost. Unless a better class of material and workmanship can be secured, the asphalt surface will require to be renewed three or four times at least during the lifetime of the concrete foundation, so that in the end the pavements will cost double the amount of the original estimate.

We believe that had vitrified brick been used on these streets instead of asphalt, the result would have been much more satisfactory in every way.

OFFERING BRIBES TO ARCHITECTS.

WE have more than once called attention to the reprehensible practice of some manufacturing companies who, instead of relying upon legitimate business methods and the merits of their goods, aim to secure contracts by offering commissions and other forms of bribes to architects. A well-known firm of architects in Western Ontario lately received a barefaced offer of this kind, which they have sent to us with the request that we would assist to put a stop to the practice. Believing that exposure is one of the most effective means to this end, we print the communication in full, as follows :—

DETROIT HEATING & LIGHTING CO.

DETROIT, Mich., April 7th, '96.

Messrs. —
—, Ont.

Dear Sir :

As we conduct our business for profit, we assume that you conduct yours from a like motive. We propose to increase our profits by adding to yours, and, therefore, submit the following proposition for your consideration :

More than ten years ago, we began to manufacture hot water and steam heating apparatus. Such work was not then understood by the local fitter, and, in order to bring such systems into general favor, it became necessary for us to employ a force of about one hundred expert hot water fitters for installing the systems all over the United States ; a force of about fifteen engineers and draftsmen, for preparing plans, and about thirty traveling salesmen, to drum the country. The situation has now completely changed, in that : 1st, we no longer contract for the installation of such systems, and, consequently, do not carry a force of traveling fitters. 2nd, the local fitter is now familiar with the work, therefore, it is no longer necessary to employ a force of engineers and draftsmen. It is admitted that the present price on first-class heaters is too high, but manufacturers still maintain present high prices, because they continue to employ, at a heavy expense, a large corps of fitters, engineers, draftsmen and drummers.

Our heaters are well and favorably known all over the United States, and, as we now sell them only to local fitters, we propose, (allowing other manufacturers to conduct their business as may seem best for them), to dispense with our large force of engineers, drummers, etc., and divide the saving thus effected with the local fitter and architect : 1st, by offering our heater to the fitter at a lower price than any other first-class heater in the country ; 2nd, by paying to the architect a commission of 10 per cent. on net sale price of the heater specified by him, if sale is finally effected. Therefore, after this date, our representative will not visit you, as has been his custom in the past.

We trust you may be pleased to co-operate with us in the plan outlined above, and if so, to avoid errors or misunderstandings, when you specify our apparatus, will you kindly fill out the memorandum in the enclosed book, and forward to us, without delay, so that we may place on file, and when transaction is fully completed, we will remit, or protect your draft on us, for the amount of commission. This proposition also includes our Combination gas machine, at a commission of 5 per cent., net amount sale, up to, and including, seventy-five (75) lights, and 4 per cent. on one hundred lights, and larger.

We know that our plan of dividing profits will prove mutually profitable, and hoping that we may have your early reply, indicating that you will co-operate with us, we remain,

Yours very truly,

DETROIT HEATING & LIGHTING CO.

P. S.—Price lists and discounts on application.

The form of memorandum above referred to is as follows :

Owner of Building	Date .....
.....	Specified by Architect .....
Capacity Gas Machine	State and City .....
Heater Specified, No.....	Address of Owner.....
Date Advised D. H. & L. Co.....	Heating Contractor's Address.....
Heating Contract awarded to	Lighting Contractor's Address .....
Lighting Contract awarded to	Capacity or No. Heater .....
.....	Capacity or No. Gas Machine .....
Detroit Heating and Lighting Co., Detroit, Mich.	Mail this to Detroit Heating and Lighting Co., Detroit, Mich.

It may be that some architects do not scruple to receive and accept offers of this kind, and that the idea has consequently got abroad that all architects are open to do business on this plan. If so, the impression is a false one. We believe the leading architects of the country are guided in their practice by higher principles, and that an offer like the one printed above would be considered a sufficient offence to warrant the exclusion of the person making it from tendering upon future contracts. It is still true that honesty is the best policy.

MOVABLE FOUNDATIONS.

PROF. JOHN MILNE, of the Imperial College of Engineering at Tokio, Japan, has devised a novel form of foundation for buildings erected in countries subject to earthquakes, involving the use of huge ball bearings. About half a century ago a Japanese builder became convinced that the secret of protection rested in the foundations of buildings, and erected an immense bamboo structure on wooden beams resting on long iron rollers. Upon the occasion of the first earthquake the structure rose and fell with the undulations of the earth, but as soon as the trembling changed the building collapsed, for the reason that the rollers could only move one way. He next erected a building equipped with two sets of rollers, one above and at right angles to the other. This was more successful. At a later date, Prof. Milne, in taking apart a bicycle, noticed the ball-bearings at the axles, and erected a building on this principle, making the walls with a groove at the base and resting them on rows of iron shot and balls. These in turn rested in grooves running in all directions, so that the house could move to and fro. This experiment proved entirely successful, and while the building swayed in a startling manner it did not collapse.

EXAMINATIONS FOR BUILDING INSPECTORS.

THE following questions were set at the late examinations for building inspectors, both for iron and steel-work and for the general inspection of buildings, by the Civil Service Board of New York :—

TECHNICAL—MARCH 10, 1896.

1. State in full (giving their names) what drawings are in your opinion needed to give an inspector the information he should have to properly inspect a building.

2. Is it part of the duty of an inspector to examine the specifications of a building he is in charge of, and for what purpose in general?

3. What is the very first thing an inspector has to do in connection with the preparation for a building about to be erected, and how should he perform that duty? (State this in detail.)

4. Suppose that shelving rock be found in making the excavation for a building, what must be done?

5. What accidents are liable to happen in making the excavation for a building, and how are they to be guarded against?

6. Suppose the ground under one portion of an excavation to be loaded to 10 tons per square foot, and that under an adjacent part of the same building to have 5 tons load, what will be the result?

7. When you wish to build strictly sound stone masonry, state every detail of the process and every precaution you must use. (This does not refer to the cutting.)

8. State what are the characteristics of a strictly well-built brick wall, and all the details necessary to be observed by the mason in building it; including the inspection of the materials.

9. Give every detail of the mixing and placing of first-class concrete, (1) cement, (2) sand, (3) gravel or broken stone, including the inspection of the materials.

10. Is it a good plan to cement closely the ends or other portions of timber? Give a reason for your opinion.

MARCH 19, 1896.

11. Will painting, cementing or tarring timber prevent decay? State all you know about it.

12. What are the objections, if any, to the use of grout in masonry, where other methods can be used?

13. Add the following measurements together, 10 feet 9 inches, 13 feet 7 inches, 15 feet 2 inches, 12 feet 11 inches, 17 feet 1 inch, 23 feet 8 inches.

14. Subtract 27 feet 9 inches from 97 feet 5 inches.

15. Multiply 19 feet 5 inches by 6.

16. Divide 99 feet 7 inches by 5.

Six additional questions will be asked verbally respecting plans of buildings.

MARCH 17, 1896.

1. Suppose the excavation for a building to be completed, how would you determine whether the earth or other natural material under the foundation was suitable to found upon without further preparation or work?

2. Suppose rock to be exposed in making an excavation for a building, and that it slopes considerably so that its surface under a portion of the foundation runs below the level at which it is proposed to start the foundation, what should be done?

3. What matters would you expect to find described in the specifications for a building which are not usually given on the drawings or plans?

4. What is the reason for making the footing of a wall wider than the wall itself? Also, is there any reason for ever making this excess of width greater under one building than under another of the same dimensions?

5. Suppose a brick building to be 50 feet by 100 feet and 45 feet high, and to have no cross walls ; and that, while putting on the roof beam one of the bearing walls shows signs of weakness, what steps should be taken to prevent accidents?

6. Describe fully the operation of cutting an opening through a bearing wall in a safe manner?

7. Suppose the ends of wooden floor beams to be left square where they enter a bearing wall, what objections are there to this method, and what danger may result?

8. What is the object of filling the space between the floor and ceiling in partitions?

9. Suppose an old brick wall is to be lined with a new one to make it heavier, how can you make the two work together?

10. In putting timbers under the wall of a building for the purpose of underpinning it, how do you tell when the wedges on the timbers are driven up sufficiently or sufficient strain taken on the lifting screws?

11. What makes the most solid work, cement mortar or cement grout, and for what reasons?

12. In the following specification for stone masonry, state what important omission there is.

"Stone to be found, free from weathered faces, beds to be full and square to face with no large pitch holes, exposed faces to be pitched true, to be laid in cement mortar mixed 1 cement to 2 clean sharp sand, all joints to be ⅜-inch and thoroughly filled, the stones to be bonded as shown in the drawings. The wall to be laid true and plumb, and all joints to be cleaned out for 1 inch from the face and thoroughly pointed with rich cement mortar."

13. Give, in your own language, every one of the requirements needing the attention of an inspector to insure that the brickwork in a building shall be as good as it can be made?

14. State what you know as to the best methods of protecting iron floor beams from damage by fire.

15. State what you consider the best method of protecting iron columns against fire.

16. What are the causes of dry rot in timber?

17. How would you know from the plans what materials were to be used in the walls of a building?

18. What is a transverse section?

19. To what drawings would you refer to determine the construction of floors?

20. What do the various colors on plans denote?

IRONWORK—MARCH 10, 1896.

1. What should be the finish of the ends of all columns or parts of columns to insure sound and plumb work?

2. How would you proceed to make a careful inspection of wrought-iron columns, girders, &c., before erection?

3. Suppose that in the erection of wrought-iron work some of the holes for rivets do not come fair with each other, what is the correct procedure?

4. How should the head of a rivet look after it is driven, and what test should be applied to rivets?

5. Can a rivet be driven tight if the plates to be joined are not in absolute contact? If not, why not?

6. Are bolts as good as rivets for fastening the parts of iron work together? Give your reasons for so thinking.

7. Is ironwork ever damaged in transportation? State what you know about it.

8. Does the wind ever displace or damage ironwork after its erection and before completion, and what provision, if any, should be made against such damage?

9. Are the floors of a building ever damaged during erection by overloading, and in what way does the damage show itself?

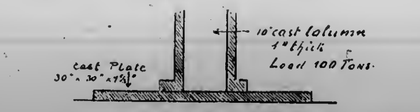
10. In which way is a rivet the stronger when sheered by a side strain or pulled endwise?

11. Could you tell with a cold chisel whether a piece of steel in a girder was soft and tough or hard and brittle, and how?

12. How would you inspect a cast-iron column if called upon to do so?

13. Criticise the following details of the tops of cast-iron columns and give your reasons for your conclusions. State also what should be done to make the one marked "A" correct.

14. How would you change the following base, &c., of a cast-iron column to make it safe?



15. In addition to the above, six questions will be asked verbally in connection with a set of plans.

MARCH 17, 1896.

1. Is there any objection to the use of "shims" in plumbing columns or parts of columns? If there is, state it.

2. State some of the dishonest expedients proposed by work

men at the shops used to hide bad work and mistakes, or to cover flaws or other defects in wrought-iron work?

3. Is "drifting" rivet holes a good thing to do when they do not meet? Is there any other course to pursue, or is this the best?

4. What are the characteristics of the best work in riveting?

5. Does it make a difference in the quality of rivetting whether the blows struck in driving the rivets are light or whether they are heavy?

6. State the requirements for the best work in the use of bolts for fastening the parts of ironwork together.

7. Is ironwork ever displaced or damaged after its erection and before the completion of a building, and in what ways?

8. Suppose the floors of a building to be too heavily loaded with material during erection, how would you expect to discover that they were so loaded?

9. Have you ever seen cases where the fastening of floor beams to girders was insufficient; if so, how did you know it was insufficient?

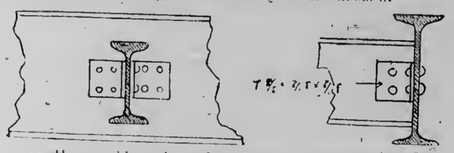
10. How would you test a piece of steel in a girder, &c., to tell whether it was soft and tough, or hard?

11. What defects are cast-iron columns subject to, and how would you proceed to discover them?

12. What is the very best way of protecting iron which is below the water-line in a foundation from damage by rust?

13. Is there ever occasion to provide for the expansion or contraction of iron roof trusses? If so, state when it is necessary and how it is done.

14. Is the connection shown below for joining a floor-beam to a girder of correct design? State what you know about it.



15. How would you know from the plans what materials were to be used in the walls of a building?

16. What is a traverse section?

17. To what drawings would you refer to determine the construction of floors?

18. What do the various colours on plans denote?

MONTREAL.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

VICTOR BOURGEAU.

In connection with the letter of a correspondent, the Inland Architect prints the accompanying portrait of Victor Bourgeau, who was the architect of St. Peter's Cathedral, and the designer of the altars, pulpit and organ of Notre Dame Cathedral, in this city. Many of the Catholic churches, schools and convents in the province of Quebec were erected from his designs and under his supervision. He died about three years ago, being upwards of eighty years of age.

MONTREAL SKETCH CLUB.

The Club has commenced to hold monthly competitions. The following problem has been given out for the month of May: "An Entrance to a Public Building leading directly from an open court to a large hall." Drawings must be sent not later than the 29th inst. The students one Saturday afternoon recently visited the Canada Life Building, now in course of construction. The meetings of the Club are well attended.

EAST END C. P. R. DEPOT.

Workmen are at present engaged in clearing the site for the proposed C. P. R. east end depot. Considerable work is to be done on the building this season.

P. Q. A. A.

The series of lectures in connection with the monthly dinners of the P. Q. A. A. was brought to a close on the evening of the 14th of April by a lecture by Mr. W. E. Doran on "Truth in Architecture." The Association held a general meeting on the 12th ult. to consider preliminaries in connection with a proposed Architectural and Arts and Crafts Exhibition to be held in Montreal next fall in connection with the annual meeting. A general committee has been organized to complete arrangements, and will hold its first meeting on Tuesday, the 19th prox.

SANITATION AND HEATING

PLUMBERS' SUPPLY MERCHANTS ORGANIZE.

A MEETING of manufacturers of and wholesale dealers in plumbers' supplies was held in Toronto on Tuesday, May 5th, to consider questions affecting the trade. The meeting was the result of certain concessions asked for by the Master Plumbers' Association. The attendance was representative, and included the following:

A. A. McMichael, Jas. Robertson Co.; James Morrison, James Morrison Brass Mfg. Co.; A. J. Somerville, Ontario Lead and Barb Wire Co.; A. D. McArthur, Craig & McArthur; John M. Taylor, Toronto Radiator Mfg. Co.; W. H. Carrick, Gurney Foundry Co.; H. S. Hergert, M. & L. Samuel, Benjamin & Co.; J. H. Patterson, Toronto Hardware Mfg. Co.; H. W. Anthes, Toronto Foundry Co.; A. G. Booth, Toronto Steel-Clad Bath & Metal Co.; W. B. Malcolm, W. B. Malcolm & Co.; Geo. Booth, Booth Copper Co., all of Toronto; E. Smith, Robert Mitchell & Co., Montreal; Geo. McAvity, T. McAvity & Sons, St. John, N. B.; T. A. Stevens, Stevens Mfg. Co., London; W. Armstrong, Essex Brass & Iron Co., London.

The necessity of organization, in order to more effectually carry out the objects desired, was apparent, and at the suggestion of Mr. Somerville, it was resolved to form an association, to be known as the Association of Manufacturers and Dealers in Plumbers', Steam and Hot Water Fitters' Supplies. Temporary officers were elected as follows: A. A. McMichael, president; A. J. Somerville, vice-president; A. G. Booth, secretary.

A committee was appointed to draft a constitution and by-laws, and a report therefrom will probably be presented at a meeting to be held on the 21st inst. A resolution was passed pledging the members of the Association to supply goods only to legitimate master plumbers and steam fitters.

The Association gives promise of developing into a strong organization. It is intended to represent the whole Dominion, and already a majority of the largest manufacturers have signified their intention of becoming members.

The organization of a Master Plumbers' Association, at London, Ont., has been effected, after a determined effort on the part of the promoters. The officers-elect are: W. J. Hazlett, president; W. Smith, first vice-president; W. J. Skelley, second vice-president. The Association held its initial banquet on May 19th, at which Mr. W. J. Burroughes, president of Toronto Association, was present.

The Master Plumbers of Toronto must have had a very good time at their recent convention, judging from the reports which we have read, says the Chicago Master Steam Fitter. At the banquet following the business session about 150 guests were present. During the toasts and speech making considerable merriment was caused by numerous amusing stories told on the plumber. Amusing stories did not occupy all the time, as the members seem to have had an eye to business and the welfare of the association at all times, and many of the jokes contained a strong business pointer.

He who refuses to consider heating and ventilation together, as a part and parcel of the same art, is not likely to achieve much in his efforts at improvement, says Domestic Engineering. In all future attempts at advancement in heating or in ventilating appliances they must be considered together. Good heating of buildings cannot be attained without ventilation, neither can good ventilation be obtained without heating. As well try to consider the steam engine alone, or the steam generator alone in the art of gaining power from steam as to separate the twins, heating and ventilation. No house, heated independently of the aid of airflow, is well heated. The ventilation of a building in winter without warming the inflow would not be good ventilation.

STUDENTS' DEPARTMENT.

"CANADIAN ARCHITECT AND BUILDER" STUDENTS' AND DRAUGHTSMEN'S COMPETITION.

THE publisher invites from architectural students and draughtsmen, other than practising architects, designs for front cover page for the New Year (1897) Number of the CANADIAN ARCHITECT AND BUILDER.

Designs must be rendered either with pen and perfectly black ink or with brush in sepia on a sheet of white drawing paper or card-board, drawn to the size or 22 × 14 inches, and capable of being reduced to 7 × 11 inches. The wording to appear on the design is as follows:

"CANADIAN ARCHITECT AND BUILDER.
NEW YEAR NUMBER. 1897. TORONTO, CANADA."

Drawings must be marked only with the motto of the author, and accompanied by the motto, full name and address of the author, in sealed envelope, must be sent, charges paid, addressed to the publisher of the CANADIAN ARCHITECT AND BUILDER, Toronto, so as to reach this office on or before 5 o'clock p. m., on Monday, the 6th of June next.

This competition will be decided by a majority vote of a committee of architects to be appointed for that purpose by the Council of the Province of Quebec Association of Architects and of the Ontario Association of Architects. The decision of this committee will be final.

If two or more suitable designs are submitted, a prize of $10.00 will be given to the author of the one awarded first position and $5.00 to the one awarded second place. The right is reserved to withhold the prizes if two or more suitable designs are not submitted. The right is also reserved to publish any of the designs submitted.

NOTE. This competition is announced with the object of testing somewhat outside the lines of their every day work the artistic skill of Canadian students and draughtsmen. It is hoped that the response will be generous and earnest, and the result satisfactory.

PERSONAL.

James Hobbs, a well-known builder of Hamilton, Ont., is dead.

Mr. Kivas Tulley, chief architect of the Public Works Department of Ontario, has been succeeded by Mr. F. R. Heakes, formerly assistant architect. Mr. Tulley has been retained as consulting architect and engineer.

Mr. J. B. Resther, senior member of the architectural firm of Resther & Sons, Montreal, and a leading member of the Province of Quebec Association of Architects, died on the 14th inst., after a brief illness. He was sixty-six years of age, and had been a resident of Montreal for many years.

The death occurred in Toronto, on the first of May, of Mr. William Hynes, at the age of 69 years. In his earlier days Mr. Hynes was a prominent contracting plasterer, being a member of the firm of Hynes Bros., who carried on business from 1840 to 1875. During that time contracts were executed in many of the best buildings of the city, among which were Osgoode Hall, Toronto Insane Asylum, Customs House and R. Walker & Son's store.

ELECTRICITY IN STONE QUARRIES.

IN Europe electricity is being largely used in the operation of stone quarries, and is claimed to have many advantages over steam power. A French writer has recently made comparisons showing the efficiency and economy of the two systems. Concerning the steam plant he says: Suppose we have a boiler evaporating 8.5 kilograms per kilogram of coal. A good machine of 300 horse power requires not more than 6.5 kilograms of steam per horse power indicated. This will give an additional horse power for every 765 grains. The transformation of mechanical into electrical energy means 6 per cent. loss; add to this 7 per cent. lost in conductors, and absorption in receiver of 7 per cent., and there is a total loss of 23 per cent. Suppose we have a stone saw motor of 20 horse power, the central machine will develop 30 effective horse power, or about 33 indicated horse power. The consumption of coal then will show a total of 610 kilograms per 24 hours.

In the old method condensation was responsible for much loss of valuable power, and the great item was the enormous consumption of coal in comparison with the amount of work done.

On the other hand, with electrical apparatus the principal generator only absorbs an amount of energy proportioned to the work. Other advantages are fewer employees, and consequently a smaller percentage of accidents, the prevention of many breakages, while the speed of the machinery is more readily controlled.

The electrical system of operating their quarries was adopted about two years ago by the Hainaut Quarries Company, at Soignies, Belgium. The quarries of this company cover an area of 96 acres. For the handling of immense blocks a travelling crane of 60 tons capacity is actuated by an electric motor. A second motor is at the bottom of the quarry for drawing the blocks away from their bed. A travelling crane of 10 tons capacity is moved by a third motor. All the machines are shunt wound and have reversing rheostats. The system is said to have given entire satisfaction.

SOLAR ROOM, STOKESAY CASTLE.

NOTE. The design for a summer hotel, by Mr. G. A. Monette, architect, published in the ARCHITECT AND BUILDER for April, is to be built shortly at Grosbois Island, opposite Boucherville, Que. The building has a frontage of 120 × 100 feet, and will contain about 120 bed-rooms, with all modern conveniences. It has been so planned that a part of the hotel may be used in winter and the other part closed. The exterior will be clap-boarded and shingled, with panels in rough-cast work.

The James Smart Manufacturing Co., of Brockville, Ont., in their advertisement in this number, print some particulars of the Kelsey Warm Air Generator, of which they are the exclusive manufacturers for Canada.

MANUFACTURES AND MATERIALS

CANADIAN SLATE—ITS FORMATION, EXTRACTION AND USES.*

THE growing importance of the slate industry of Canada demands a consideration of the utility and value of the mineral, its occurrence and distribution, especially in the province of Quebec, and the method of extraction and usage. The subject is so comprehensive that adequate justice cannot be given to it in a short paper of this kind. I find nothing written upon the subject except the meagre references made in Geological reports of Sir Wm. Logan and others. Therefore, as no thorough examination has been made of the slate formations of this province, our knowledge of the same must be limited. No clay slate of any value is found in the Laurentian range nor anywhere in the Province of Ontario. In coming east through the Province of Quebec, we find the first slate formation near Stanbridge, and this appears to be a continuation of a similar slate found in an island in Lake Champlain, and also in Hatch Hill, south of Whitehall, in New York State. No work has been done on this vein except on the island above mentioned. Then farther east we strike purple and green slate in Missisquoi county, and at Granby, where some small openings have been made. This formation continues to the north-east to Actonvale, where a quarry was opened and operated by Mr. Rankin, of Montreal. Then we come to the Kingsby formation, which is a very wide purple and green belt. A quarry was opened on this vein at Trenholmville, but the slate that was produced was of poor quality. This formation is different from all the others, it being a laminated formation, the bedding about one-quarter inch and more apart, and not capable of being split between the beddings. A slate of similar character is found in Birds-Eye Mountain, near Castleton, Vt., which possibly is a continuation of the same formation. East of this are the Melbourne veins, upon which several openings have been made, to wit, Melbourne quarry, the New Rockland quarry, which is now being worked; the Steele quarry in Cleveland, and the Danville quarry in Shipton. Slate of excellent quality is being produced from this vein. The next formation east of this is found near Windsor Mills. It is an extensive deposit, but owing to its ribbony character, the ribbons in it being hard and occurring at intervals of only a few inches, renders it unworkable and of no value. Next we come to the Brompton formation, upon which two openings were made near Key Brook, about thirty-four or thirty-five years ago, but this also is full of ribbons, which unfit it for the production of roofing slate. Slabs for sidewalks and cellar bottoms have been taken out of it at several places which at a greater depth would be good for that purpose. This formation is very extensive, being about a mile in width at Brompton. It is identical with the beds at Montpelier, North Johnsbury, and also Guilford, south of Brattleboro, Vt. Quarries have been opened in each of these places and were wrought for many years, the Brattleboro or Guilford quarries being undoubtedly the oldest on this continent. They were worked as far back as 1812. This vein runs south of Guilford for about ten miles when it is pinched out by the granite. Then we come to the information of East Angus and Garthby and several veins of different colors in Beauce county. From the number and variety of the slate deposits of Quebec, it would appear that many remunerative quarries might be opened.

The main ingredients in the composition of slate are silica and alumina, which show it to have been at one time ordinary clay. Blue (of different shades), purple red and green are the ordinary colors met with. The blue color is derived from the presence of protoxide of iron, or iron and oxygen mixed in the proportion of one part of the former to two of the latter. The red and purple varieties take their color from iron in the form of peroxide, two parts of iron combined with two of oxygen. Into slate of a green color, which is the best common variety, iron less largely enters, and in combination with magnesia, gives them a greenish hue. The clay beds were deposited in ages long past, in the bottom of the sea, and in process of time they have been hardened into stone, and lifted up so as to form dry land. That these beds were originally deposited in the sea, geological authorities mention among other reasons the fact that they contain abundantly the remains of former sea life, which lie along the planes of the bedding, such as zoophytes, mollusca and crustacea. The fossils of these strata may be studied from Sedgwick and McCoy's "Palæzoic Rock and Fossils," and other works. The presence of soda and potash in the slate deposits, being the record of the saltness of those ancient seas, is an additional proof of the beds of clay in the sea. It can be well imagined how when this deposition was made that it went through a process of sorting. The heavy, coarser material would be deposited first near to the shore; the finer matter would be carried farther to the sea, and the lightest portions of all would be held longest in solution and would reach the farthest from the shore line. We can well understand then that the variations we find in the quality, color, consistency and thickness of the strata, etc., are all due to the disturbance of the water, caused by oceanic and tidal currents, as well as by storms, which then as now occurred periodically. As a result of these storms we might naturally expect to find, even in the finest deposits, layers of coarser material.

From these simple statements relative to its formation it will readily be seen that in a slate bed which extends over miles of country, a great variation in consistency and color will be found. The deposition of the coarser or finer portions will determine the former, while the latter is dependent on the presence in the water of the different oxides of iron in combination with carbon, when vegetable growth has occurred, magnesia and other elements, it will be seen also that it is fallacious to suppose, that because a vein has been proved good or bad in a certain portion, that it must necessarily continue the same throughout its entire course. Each particular portion must speak for itself only. In all slate veins, lines, or bands, sometimes wavy, but oftener straight, will be seen crossing in. These are lines of bedding, and it does not follow that the lines of cleavage will coincide with them, as it can only be supposed that the phenomenon of cleavage resulted from an action which occurred long subsequent to the deposition of the muddy layers in beds. There is some difference of opinion among those who have given attention to the subject as to the manner in which this slatey cleavage was produced. It is explained by some to be the result of a crystallizing action; by others to be due to magnetic currents, while others, again, claim it to be the effect of mechanical forces that compressed the sediment at right angles to the direction of cleavage always at right angles to the dip of the vein.

The occurrence of joints, such as floor or foot joints, face or side joints is accounted for by the mass slowly hardening and consolidating by pressure as well as heat. Lifted out of the water it cracked and split in various directions in drying, and, influenced by the law of crystallization, it assumed definite shapes, being split into rough and rhomboidal masses. Had our original deposition been homogeneous and subsequent action constant and uniform our present slate veins would all have been practically perfect; as such, however, was not the case we have to contend against many conditions which determine its possibility of being worked to advantage. The presence of dykes, posts, wavy cleavage, impure beds, etc., we find in all slate formations, and it is only after a careful and intelligent study of the conditions that we are enabled to know of its value.

The industry in the Province of Quebec is at present confined to the workings of but two quarries. One operated by the New Rockland Slate Co., at New Rockland, and the other by the Danville Slate Co., near Danville. Both these quarries are located on what is known as the Melbourne vein, previously mentioned. The former is the most extensively worked of any that has been opened in Canada. Here the rock stands nearly straight, having a dip of 80° to the southeast. The slate is of excellent quality, being hard, tough and strong, and blue-black in color, which is unfading. It is of compact and close grain, admitting of no soakage of water, making it very durable.

The first workings were opened about 1865, on what is known as the west bed, lying in the serpentine rock. Operations were entirely confined to this bed until the year 1881, when a cutting was made through a hard bed, and a body of slate found which was equal in quality to that of the other vein. Operations have continued in this new vein up to the present time. This vein is very regular in formation, not being intersected by any foreign rocks, but parts of it are very subject to chicks, or an unsoundness known as slants by quarrymen, which chicks, running at an angle with the cleavage renders it unworkable for roofing slate or slab work.

A very extensive quarrying and milling plant is in use. The Salmon river here affords a very excellent water power, which is conveyed to the hoisting engines and mills by means of wire rope transmission. Cable derricks of the Blondin system are extensively used. A large mill, 100×60 feet, thoroughly equipped with all modern milling machinery, produces slab work of all descriptions. A narrow gauge railroad, about five miles in length, connects this quarry with the Grand Trunk railway, at a point about five miles east of Richmond.

At the Danville quarry the vein is intersected by a series of hard ribbons, which, however, are at a sufficient distance apart to enable slate to be made from between them. The equipment here, though on a much smaller scale, is similar to that at New Rockland, except, that the power used is steam. In addition to their roofing slate and slab work, school slates are manufactured.

Owing to the private character of the companies operating I am not able to give satisfactory statistics of the industry. The trade, however, has grown to be a very important one. This has been due principally to the efforts made by these companies to introduce slate, by the opening up of the country with railroads, and by the protection which the government has seen fit to bestow upon it. So rapidly has the trade grown of late that the demand is far in excess of the production, and with the extensive deposits of slate that we have in this country, there is every inducement for a thorough examination of the various veins, which I do not doubt would lead to the opening up and working of several remunerative quarries. And I look forward to the time, in the near future, when slate quarrying shall have become one of the principal industries of the province.

* Abstract of paper by H. J. Williams before the General Mining Association of the Province of Quebec.

GRANITE CUTTING APPARATUS.

IT is necessary in order to lessen the cost of production and withstand the inroads of competitors, that manufacturers of materials should employ such machinery as will produce the maximum of results at the minimum of cost. That Messrs. McIntosh & Sons, of Toronto, fully realize this is shown by the introduction, in connection with their granite and marble works, of what are said to be the first pneumatic hammers in use in Canada for dressing purposes. The apparatus, although simple, is quite expensive, which, together with the fact that it is not generally known, no doubt largely accounts for the fact that its adoption has not become more general.

A Northey pump forces the water up from the well to a compressed air pump, the power being supplied by a 15 h.p. engine. From this pump the air is forced through a common iron pipe to an overhead reservoir, from which the pipe extends around the building in which the carving is executed. Dropping from this pipe at different points are lengths of common garden hose, through which the compressed air passes to the pneumatic hammers. These hammers are of the most delicate mechanism, being only about one foot in length, and are controlled by the workmen in the same manner as ordinary hand work. The air operating on the hammer forces to and fro a pinion in the centre at the rate of 250 strokes per minute.

Five of these hammers are in operation at the works of the above company, the cost being about $100 each. The compressed air pump cost upwards of $300. All the apparatus is of American manufacture, having been purchased in Illinois. It is claimed that by the use of one of these hammers a workman can accomplish three times as much as by the old hand method, while the work is also of a much finer quality. In the United States these hammers are being extensively used, but they have only recently been adopted in Great Britain.

A company has been formed at Chatham, Ont., with a capital of $300,000, to manufacture a patent elevator.

The Crown Pressed Brick Company are building another patent dry kiln at Ormstown, Que., for burning dry pressed brick.

Messrs. Seaman, Kent & Co., Toronto, have recently had printed an attractive illustrated catalogue relating to their sliding and venetian blinds.

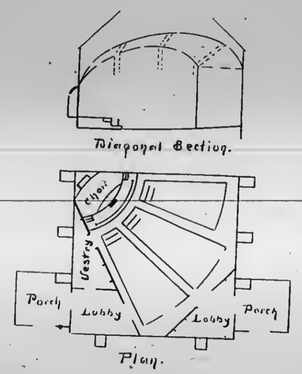
During the year 1895 there were received at the port of Montreal by vessel 146,971 barrels of cement, showing an increase of 4,599 barrels as compared with the previous year.

Arrangements are being made for the transfer of the pottery works at St. Johns, Que., to a French company, known as the Comptoir Ceramique Francais. This company controls all the pottery works in France.

The Diamond Brick and Tile Company, of Kansas City, U. S., have been experimenting with Manitoba clays for the purpose of ascertaining their adaptability for the manufacture of vitrified brick for street paving purposes. The tests thus far have not been satisfactory.

SOUND IN ITS RELATION TO BUILDINGS.

THERE is, perhaps, no subject connected with building on which so little exact knowledge is obtainable as that which forms the title of this article. The experience of architects and builders in past ages seems not to have evolved fixed laws by which the designer of a building may certainly know what its acoustic properties will be. Only to a limited extent is the operation of sound understood—beyond that all is guesswork, and the individual designer must choose his own theory and experiment for himself. It is not surprising that under such conditions, failure is more often achieved than success.



Two years ago, at the annual convention of the Ontario Association of Architects, Mr. D. G. Baxter, of Stratford, presented a paper on this subject, in which some original theories were advanced and evoked favorable comment. Our readers will doubtless be interested to learn that Mr Baxter proposes to put these theories to a practical test in connection with a Methodist church to be erected at Wellburn, near London, Ont. The auditorium of this church will be funnel shaped with the object of securing the best acoustical effect. The interior will be like the accompanying sketches, while the outside will not be noticeable from the added wings. We invite an expression of opinion from our readers concerning this new departure in church design. Indeed, a statement from a number of our readers of their experience in this direction, would prove an interesting and helpful feature.

The Royal Institute of British Architects are showing recognition of the importance of this subject by instituting a series of enquiries with a view to collect and record fuller information than is at present obtainable. The enquiries are as follows:—

1. PLAN.—Give a general plan, with elevations and sections of the interior of the building.

2. MATERIALS.—Describe the materials of which the building is constructed, carefully noting the finish of the interior surfaces and the disposition of carpets, hangings, or other similar fabrics.

3. CONSTRUCTION.—The construction of the building should be described as fully as possible.

4. SEATING.—Illustrate the method of seating by plan and section.

5. SPEAKERS, ETC.—Show position of speakers or musicians in relation to the audience.

6. EFFECT OF AUDIENCE.—The effect of an audience should be carefully noted. State if the room is better if partially or entirely filled.

7. VENTILATION.—Describe in some detail the system of ventilation. If possible, note the mean and extreme temperatures and the effect of the variation produced by it and by changes in direction of the ventilation. State the position in which the thermometers are placed.

8. KEYNOTE.—If the keynote of the building is known, state it, and say whether or not, if the voice is pitched in this key, any improvement in sound is noticeable.

9. QUALITY OF SOUND.—(a) State what is the general reputation of the building for (1) Music; (2) Speaking. (b) State what the quality of the sound is—full and resonant, &c., and note any peculiarity of effect, such as echoes and the like. (c) If defective, state the nature of the defect as carefully as possible.

10. REMEDIES.—If remedies have been tried to obviate defects, state them, and the result obtained. The precise nature of the remedy should be fully detailed.

11. ADDITIONAL PARTICULARS.—Add any particulars not above scheduled which may be considered necessary or desirable, and state age of building.

12. REFERENCES.—Give references (if any) to published descriptions of the building, especially those dealing with its acoustic properties.

13. AUTHORITY.—Give the names of the experimenters and date of experiments.

BY THE WAY.

A CORRESPONDENT sends the Inland Architect his impressions of Canada and Canadians. Much of what he writes can be classed as "rubbish," inaccuracy of statement being a conspicuous feature. As an example of the latter the following will suffice: "The Canadians are rather slow in adopting novelties. Their elevators are few and far between, and are looked at askance by many yet who would as soon attempt to walk upon the waters, as did Peter of old, as to trust their precious lives in one of those "bird cages." I admit that with most of these elevators it would be a saving of time for a busy man to walk, even leisurely, up or down stairs."

× × × ×

ARCHITECTS and builders were among the first to avail themselves of the advantages in the way of convenient and rapid local transit afforded by the bicycle. By means of the wheel, the expense of keeping a horse can, in many instances, be saved, while those who formerly went about on foot are effecting a large saving in time and strength. I wonder how many architects and architectural students have made a sketching tour on the bicycle. An opportunity is now afforded in this direction which every architectural student, in particular, should be quick to recognize and take advantage of. The officers of the Toronto and Montreal Sketch Clubs should endeavor to organize a series of short sketching tours during the coming summer.

TRUTH IN ARCHITECTURE.*

By W. E. Doran, Architect, Montreal.

"Magna est Veritas et prevalebit."

Architecture is capable of expressing truth in various forms. Firstly, from an historical point of view, it reveals with a veracity not to be found in written records the state of civilization, the manners, customs and intellectual life of peoples. "By their works ye shall know them." Without these records of imperishable stone, much of written history would, if it were not entirely incomprehensible, at least lose half its light and meaning. The character of a people is in no way more truly exemplified than in its architecture, and religion of all kinds has ever found in this art its highest form of appeal to human sympathy and worship. To illustrate the truth of these propositions it is sufficient to glance at a few of the leading historic styles and the stories they convey. Leaving aside the architectural remains of earlier peoples, and commencing with the Egyptian, had we never read a line of their history, their architecture tells us of mysteries, a learned few, an ignorant mass, a history of work achieved by automatons in the hands of a priesthood which ruled by mystery, and pretended to occult powers.

Turning to Greece we find written there freedom and enlightenment, the expansion of the human mind keeping progress with the appreciation of the beauty of nature, and its reproduction in art. Greece discovered that there was no straight line in Nature, and she proceeded to apply the principles of curves so well that she exhausted all the higher orders of them. Everything was done intellectually, and so much so that even now we can discover new beauties in which to revel amidst her antiquities.

Rome became the ruler of the world and art had to serve the mighty mistress, but the character of the work betrays itself—her architects and artists were slaves. Mighty are her monuments; building skill existed; everything that could wait on luxury is to be found—palaces, baths, aqueducts, triumphal arches; fora—all tell their tale—a people ruled first by demagogues and then by tyrants, all the world subject at her feet, all that could tend to greatness except freedom.

In the earlier periods of Christianity we can read the history of the church in its architecture, first in the catacombs and then emerging forth triumphant at Rome seizing boldly the Pagan temples, and transforming them into places of Christian worship—consequently no marked change of style was developed.

In the east a more determined attempt was made to free Christianity from all influences of Paganism, and to create a style for itself. The result was the Byzantine; however praiseworthy the motives, the best that can be said of it is that it came as nearly as possible to success, and served to prove the impossibility of any sudden creation of a style in architecture, and to illustrate one of the greatest truths of the art, viz., that all its best results must flow from patient study of certain needs and conditions and the gradual unfolding of the best and most appropriate structures to meet those conditions; insensibly, therefore, a new style will develop, but it can never be launched forth a full-fledged creation of one man's brain, or indeed as the concerted effort of any number of men.

It remained for the incursions of the barbarians to overthrow the last vestiges of Imperial Rome in Italy; when Christianity in turn succeeded in subduing these fierce tribes unto herself, there commenced a simpler and ruder architecture, that of Northern Italy, which to my mind contained elements of great merit, but which, however, were arrested before arriving at their full development. What with the incursions of Byzantine architecture from the East, and later of Gothic architecture from Germany, the Lombardic style met with an untimely death. It seems to me much might be done by modern architects beginning where they left off, instead of following a debased Renaissance of later periods.

Passing over the Norman and other transition periods, we come to the real development of Christian architecture in what is miscalled Gothic. When the church was everywhere triumphant and faith ruled supreme, there dawned this glorious triumph of the mind, aye, and of the soul of man, because, although the term Gothic comprehends so many different styles peculiar to the various countries of Europe, there was to be found everywhere a certain development, though not contemporaneous, still resulting always in three marked periods, viz., early or simple, middle or perfect, and highly florid or debased. It is of the middle period generally that I speak, and I think of that middle period in all lands it may safely be said that it exemplified all that was spiritual in our nature, not merely copied, as was the beauty of the ancients, from the book of Nature, but founded on geometrical truth and associating therewith Christian symbolism and mysticism. The Gothic architects succeeded in raising to God temples, built, it is true, by human hands, but one of these grand old cathedrals, with its misty heights, its spires and pinnacles, its niches and saints, might be easily associated with the New Jerusalem coming down from heaven.

In juxtaposition the Moslem on the ruins of the Byzantine constructed an architecture embodying all his ideas of a sensual heaven.

Leaving aside for the moment the historical view, there is another form in which architecture is capable of expressing truth, and one which concerns us more particularly as practitioners of the art, it must be based on the principles of truth. In the first place, a building or structure of any kind must adequately serve the purpose for which it is intended, and must to a certain extent be indicative of that purpose; all its parts must be harmoniously blended together, and each part must have the relative importance to the whole which its rank or office demands; thus, although there are certain established proportions which are or should be applicable on general principles, each structure also has particular proportions which depend on the skill of its designer and his perceptions of this law of truth which should govern.

In the hands of a master the observance of this rule will probably develop a new type or style, more particularly when the conditions under which the structure is to be erected, the materials to be used, or the climatic influences it may encounter are altogether novel, but more frequently the case is that this consideration leads to expression in some existing style more or less modified according to circumstances. It follows that the choice of style should never be arbitrary, and that some at least of the conditions under which it was originated must be existent in the structure which we wish to clothe with its features.

Unless an architect reads aright the story told by a certain style, and be familiar with its origin, he cannot intelligently use it. Having stated that perfection existed only in two historic styles, viz: Pagan or Natural in the Grecian, and Christian or Mystic in the Gothic, you might, at least, if you were not architects, expect me to denounce all others as vain and unprofitable, and declare that the battle of the styles should rage round these two alone, but the history of the Renaissance delivers me from this seeming dilemma.

As the cause of the Renaissance so called is a very much debated question, and would in itself require a lengthy research, I will only touch on facts which are generally admitted. That it had its origin in Italy was natural, as its people having the old monuments before them, though never studied, and serving rather as quarries for their new buildings than any other purpose, still insensibly their minds must have been affected by these remains, so much so that their Gothic work is, no doubt, mostly foreign, and in every example of native Italian Gothic some traces of classicism still remain. On account of its mis-nomer "Renaissance" or "Revival," this modern Italian misled enthusiasts who, leaving the beauties of classic literature, came to the conclusion that all perfection existed in the works of the ancients, and that art of all kinds should return to its fountain head for inspiration. But that it should have been universal, displacing all national styles, and spurious as it was, conquered, the world argued that this style contained in itself something that met the wants of men, and which could not be so suitably met by any other. I think the key is in the building of edifices of several stories. The previously considered historical styles had their development mainly in temples and monuments, churches, shrines and cloisters. Architecture had not occupied itself in habitations for man, save in the palaces of Rome, and these were on a par with its temples, or at any rate never exceeded one-story; the castles of the nobility were military strongholds rather than residences. I would therefor ascribe the success of the Renaissance to the ease with which it lent itself to the dividing of buildings into stories, marking them with external orders and balustrades. It has since been demonstrated by the failure of the Greek revivalists that anything like pure classical forms would be unsuitable for modern habitations. It is true also that England for a long time successfully resisted the invasion, and sought to create in the Elizabethan an adaptation of the Gothic to modern habitations, producing certainly a picturesque effect according well with sylvan beauty, but there as elsewhere the Renaissance came to stay. Another cause of success (though this ought to have condemned it in the mind of any person with a true feeling of the grandeur of architecture) was that every detail was so reduced to rule that most any one with a fair knowledge of drawing and construction could learn the complete art. In fact the tradition still remains with a great many otherwise well educated people that all of architecture is contained within the five orders according to Vignola or Palladio. I regret to say that the tendency of the modern art school seems to confirm this, for although more latitude is given to the skill or want of it in the designer, we rarely see anything from their graduates but variations of orders, pediments and porticos; it is a remarkable fact also that many of the most successful Renaissance architects were attracted to the profession in middle life, and were in reality amateurs.

Certainly many architects of the present day can lay claim to have improved on the work of their predecessors in this particular style, but the term Renaissance is too comprehensive, and is applied equally to the carefully studied work of the man who with true classic taste tries to avoid the errors of Vitruvianism, to the mediocre compositions of the disciples of that school, and also to the meanest aggregations of walls having band courses dividing them into sections containing one or more lines of badly proportioned openings with or without decoration, the whole finished with or without cornices. Really the term has no meaning. But the question arises: What story does the architecture of the present day tell? and how is it that there is no particular style belonging to the nineteenth century, a century so prolific of improvements, the century of steam and electricity, the century of triumphs in surgery and in all that pertains to progress, and in war and destruction. Is architecture alone stationary or retrograde? Has engineering, which was formerly only a branch of architecture alone the power to advance? My answer is that the architecture of to-day reflects all these conditions of life in this century of steam and electricity. It is all high pressure—no time for calm study, no time for experimental advance; everything must go up by magic as it were. The architect must know everything, must be equally at home in all styles, be able to use all methods of construction, attend to the most trifling matters of detail, please all tastes, be an artist, a man of business, financier, lawyer, electrician, tradesman, all in one. There is no such thing as human perfection, yet the law says his work must be perfect—not only his own work, but he is obliged to see that the work of

(To be Concluded in June Number.)

* Paper read before the Province of Quebec Association of Architects.

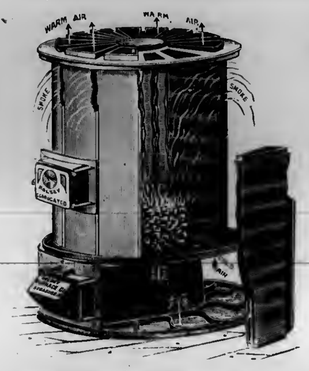
CONTRACTORS' ESTIMATES.

Omission of items in figuring contracts is probably the most common cause of disaster prevalent in building contracting, and many a good man who has intended well enough has been brought to grief because of having left out some things in his bill of estimates that ought to have been figured on. Every man who is desirous of succeeding as a contractor, should prepare a complete and minute schedule of all the items that could possibly be included in any manner of building construction. These should be classified and arranged under sub-heads, according to the different building industries or trades, and prices, where possible, should be added. By having a schedule as suggested, and consulting it closely when making up an estimate, the possibility of an omission would be reduced to a minimum.

Many careful contractors follow some such system as this in estimating, but the majority fail to see just where it would be to their interest to assist in educating other contractors to greater accuracy in figuring. It is forgotten that a contractor's ignorance or mistakes are a thousand times more to be feared in a bidding competition than accurate competency in making estimates. We know of a case in point. Bids were asked for an ordinary building. A half dozen bids were grouped closely together, varying only from $3,500 to $4,000. Then came in a bid for twenty-eight hundred dollars. In the language of the architect, "that fellow probably left off the roof, and forgot there were any floors in the building." More than one fellow has actually done such things.

If the architect could convince the owner of the advisability of rejecting such bids, when the possibility of an error is so very obvious, the demoralizing element might be thus removed, but the owner is usually hot on the trail for a bargain. He can see nothing but the price on the paper, and he thinks if the contractor has blundered that that is not his affair, and it will give him an opportunity to get something for nothing, which is generally a great mistake on his part, for in nine cases out of ten the owner gets mulcted in one way or another before the work is completed. Even when slight omissions are made in figuring the result is very unsatisfactory, for special orders for extras must be added, and these are not usually obtainable at the same rates as is paid on the main contract, and all this leads to confusion and bickering. There should be a uniform system of figuring adopted by builders in every community. Its main object should be to avoid the omission of items in figuring, and to prevent such glaring discrepancies in contractors' estimates.

Tenders for work that are not based on correct quantities, or where omissions exist, do infinite harm in many ways, and this is one reason why men who have not the requisite knowledge, should refrain from tendering for work of which they have had no previous experience. In country places, and in our villages, there are very seldom works of such magnitude that the local builder cannot encompass, but he should not forget that even in buildings of similar size, and built of similar materials, the style of finish may cost anywhere from ten to fifty per cent. more or less, so that the method of estimating by "comparison" is no more reliable than estimating by cubing, unless the estimator has a thorough grasp of all the conditions surrounding the work. There are instances, however, when estimating by "comparison" may prove fairly correct, but they are few, and in any case where one building should be contracted for at the price that a former and similar building was completed for, we should prefer to figure up the cost of the new building, item by item. There never was, there never will be, any "royal road to estimating," and the successful contractor is the man who figures up everything, and figures them up correctly.



THE... KELSEY CORRUGATED WARM AIR GENERATOR

PATENTED

The Greatest Heat Producer on the Market—
Simple, Practical, Effective, Durable and Economical

The KELSEY having such a very great radiating surface and very large capacity for air makes it possible to do the largest amount of heating with the smallest consumption of fuel.

The KELSEY will heat rooms at long distances by simply capping any required number of the upright sections with our PATENT POSITIVE ATTACHMENT, thus obviating the necessity of using a combination of hot water and hot air.

The KELSEY furnishes a nice pure fresh warm air—not a dry superheated air, as in the ordinary hot air furnace.

The KELSEY has been made and sold in the U. S. for the past eight years with the most gratifying results, and with largely increased sales each succeeding year.

Please write for Descriptive Catalogue.

The JAMES SMART MFG. CO., Ltd.

Exclusive Makers for Canada — BROCKVILLE, ONT.

E. F. DARTNELL, 180 St. James St. - MONTREAL. TELEPHONE 2382.

REPRESENTING:

Northumberland Stone Co. Brown and Grey New Brunswick Sandstone, of high grade and fine color, easily worked. Price moderate.

Grafton Stone Co. Buff and Blue Ohio Sandstones. Block Stone, Sawed Caps, Sills, Steps, Ashlar, Flagging, etc., etc.

Potsdam Red Sandstone Co. Block Stone, Flagging, Ashlar, etc. Prices quoted from specification or blue print for finished work, delivered ready to put into building, stone being cut at Prescott, Ont.

Crown Pressed Brick Co. Fine Pressed and Ornamental Bricks and Terra Cotta. Every pattern of red brick made to order. Our bricks are of a rich warm red unexcelled in quality or color by any on the market.

American Mineral Wool Co. Mineral Wool and Mineral Wool Sectional Covering. For Insulation of Heat, Protection against Frost, Fire-proofing, Insulation of Sound, Cold Storage, etc.

Dillon Cement Plaster Co. Aluminite Cement Plaster. Nature's own mixture. Most perfect plastering material known to the trade. A pure natural plaster without admixture of any kind.

Translucent Fabric Co. Translucent Fabric. The great substitute for Glass. Especially adapted for skylights and windows in factories, skylights and storm doors in houses, hot-houses, etc. Strong, Durable, Light, Unbreakable, a Non-Conductor.

CORRESPONDENCE INVITED. - - SAMPLES AND PARTICULARS ON APPLICATION

ERRATA.

In the sketch of Mr. John Aldridge, president of the Toronto Builders' Exchange, which appeared in our last issue, it should have been stated that Mr. Aldridge was a native of England, instead of Scotland, having been born at Brockenhurst, County of Hampshire.

A BOND OF UNION.

Mr. Jos. Greenfield, architect, Winnipeg, in renewing his subscription to the ARCHITECT AND BUILDER, writes: "Permit me to express my appreciation of the value of your publication as a means of information and a bond of union between the members of our profession in this Canada of ours."

VOL. IX.—NO. 6. JUNE, 1896 { PRICE 20 CENTS $2.00 PER YEAR.

—THE—

CANADIAN ARCHITECT AND BUILDER,

A Monthly Journal of Modern Constructive Methods.

(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD).

PUBLISHED ON THE THIRD THURSDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

C. H. MORTIMER, Publisher,

Confederation Life Building, - TORONTO, CANADA.

Telephone 2362.

Branch Office: NEW YORK LIFE INSURANCE BUILDING, MONTREAL.

Bell Telephone 2299.

SUBSCRIPTIONS.

The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.

Prices for advertisements sent promptly on application. Orders for advertisemnets should reach the office of publication not later than the 12th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of technical value to the persons in whose interest this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publisher of any irregularity in delivery of paper.

Improvement of the Architect and Builder.

FROM this time forward each number of the CANADIAN ARCHITECT AND BUILDER will include 36 pages of letter press instead of 28 as heretofore, in addition to the usual illustrations. The added space at our disposal will be especially devoted to information of a practical character designed to interest and prove helpful to contractors in all departments of building work. This information will be found in this and succeeding numbers under the title of "The Builder." It is hoped that this increase in size and scope will be appreciated by our readers, and lead to an increase in our already large list of subscribers.

Building Conditions.

THERE is a fair amount of activity in building enterprise throughout the Dominion, the volume of which will probably equal that of last season. On the whole, however, the work is of a less important character than last year, and the expenditure proportionately less. Toronto architects and builders have good cause to complain of the lifeless conditions prevailing in that city the present year. The number and value of buildings for which permits have been granted is greatly below the record of last year. This is in a large measure due to the fact that with one exception there have been no fires of any consequence involving the destruction of buildings. While rightly enough every precaution is taken to prevent the danger to life and property from fire, we are sometimes led to wonder what would become of architects and builders if the destroying element were put entirely under control. The amount of their occupation would be so greatly reduced that many would be forced into other callings.

What Constitutes a Party Wall?

CANADIAN architects and builders should be interested in a point of law relating to the definition of a party wall, which came up for argument in the English courts recently. A firm of store-keepers were summoned to appear in court on the charge of having violated the London building law by piercing openings in a party wall. The section of the law bearing on the case reads as follows: "Every party wall shall be carried up of a thickness in a building in the warehouse class, equal to the thickness of such wall in the topmost story above the roof-flat or gutter of the highest building adjoining thereto to such a height as will give a distance of at

least three feet measured at right angles to the slope of the roof. The wall in question divided one portion of the defendant's warehouse, one-story in height, from another portion, five stories in height. The defendants contended that only the portion of the wall to the height of the one-story part of the warehouse could properly be classed as a party wall, and that above this height it should be classed as an exterior wall. The court sustained the defendants in this contention.

Queen's Park Improvement.

THE work of improving that part of Queen's Park in front of the Toronto Legislative Buildings will very soon be completed. The large stretch of sloping and finely graded lawn, with its statues, walks, trees and flower-beds, produces a very agreeable effect. The driveway in the Avenue from Queen Street north and around the west side of the park has been entirely reconstructed since last season. This is one of Toronto's beauty spots, and it is gratifying to see it being put in a condition somewhat becoming its importance and possibilities.

The Recent Labour Troubles.

JUST as our May issue had left the press a settlement was reached between the Toronto Builders' Exchange and the builders' laborers with respect to the wage question. The latter have agreed to accept the same rate as was paid during the season of 1895, viz., 18 cents per hour, an agreement having been signed to that effect covering a period of two years from the first of May last. This step removes the possibility of any further dispute between the master builders and employees during the present season, agreements having now been signed with all the trades. This is a cause of congratulation, for while it was imperative upon the laborers to accept the offer made by the master builders, the wisdom of so doing becomes more apparent as the season advances and few new buildings are shown to be in contemplation.

School Sanitation.

WE are pleased to learn that the Toronto Public School Board has taken a very important step this season towards bringing all the school premises under their control up to a proper sanitary standard. There are still quite a number of the schools where the closets are the old-fashioned brick pit in open sheds. While they are provided with sewer outlet and kept in as good condition as possible, they are in some respects positively unsanitary. At one of the large schools these outside closets will be removed, and complete new modern water-closets will be provided in the basement of the main building, with the best plumbing work and thorough ventilation. This is the first time that such a change has been made by the Board except in case of rebuilding or enlargement of a school, and will undoubtedly be followed by the same kind of improvement at other schools as rapidly as funds for the purpose can be obtained.

What Should be Taught in our Public Schools?

WE have occasionally heard the opinion expressed that our system of public education is too liberal, in that it goes beyond instruction in the three R's. Strange to say, this opinion is sometimes heard from well-educated persons. This is on a par with the opposition of representatives of labor organizations to manual training in the public schools. Both ideas are wrong. Train the mind and train the hand of the young as liberally as can be afforded. True education need not be feared by anyone, but will prove an advantage to all. Such critics as those referred to would shut out from a public system of education such studies as drawing and hygiene. But a careful grounding of pupils in these studies develops a taste for art and an interest in sanitation, which is of positive advantage to architects and builders, as well as the public, in that it stimulates the demand for artistic and healthful buildings.

Value of Improved Fire Protective Appliances.

THE fire which destroyed one of the large departmental stores in Toronto on the evening of the 9th inst., furnished several good lessons to persons interested in city property and business. The building and stock were of a very inflammable character, and were burning fiercely before attacked by the firemen. Had it not been for the improved fire apparatus supplied to the department last year, especially the water-tower and the steam engines, the loss would have been far greater. The outlay for new apparatus was clearly saved many times over in this instance alone. Notwithstanding, had there been a fair to strong breeze the danger would have been greatly increased. Three things are indispensable to prevent the ruinous spread of such fires first, buildings constructed as nearly fire-proof as possible, consistent with their location and purpose; secondly, the best appliances for extinguishing fires; and thirdly, competent men in a well organized fire department. The first of the above mentioned requirements is first also in importance.

Safe Construction.

THE bridge failure at Victoria, B. C., on the Queen's Birthday, involving the sudden destruction of nearly one hundred lives, is a startling reminder of the necessity of proper design and construction not only of bridges but also of buildings, upon the safety of which human life depends. Especially does it emphasize the danger of putting a structure to a different use from that which it was designed to serve. The bridge at Victoria was originally constructed for vehicular and foot traffic only, but was afterwards subjected to the enormously increased strain imposed by overcrowded street cars, with what result is now sadly apparent. Since the disaster the statement has been made that the safety of the bridge had previously been called in question. Presuming this to be the case, the warning, as too frequently happens, was disregarded. Now that a large number of precious lives have been lost, and sorrow carried to hearts in every part of the Dominion, a rigid inspection of the bridges throughout the province has been undertaken. This bears the appearance of locking the stable door after the horse has been stolen, yet it is to be commended, in view of the possible prevention of like disasters, and we trust will lead to similar action being taken by the governing authorities of the other provinces. Investigation would be certain to reveal the existence of many unsafe structures of an engineering and architectural character. Periodical inspection of traffic bridges and buildings by officials of either municipal or provincial authorities, seems to be necessary for the public safety. Of even greater importance than this, however, is the need of legislation such as the Ontario Association of Architects have sought to obtain,

restricting the use of the titles "Architect" and "Engineer" to persons who shall have given proof of qualification for the work.

DEFECTIVE ELECTRIC WIRING.

To the Editor of the CANADIAN ARCHITECT AND BUILDER.

SIR,—As perhaps no part of house fitting has made such rapid headway and none is known less about by the average citizen than electrical wiring, will you kindly permit me to use your columns in giving a few hints in this direction which will be of service to the public.

Let us suppose Mr. Citizen decides to erect a house, electrically equipped for bells and light. He naturally knows little or nothing about the matter, but hands it over to the architect, who in nine cases out of ten knows less, but contents himself with inserting a few stereotyped phrases in the specifications, which he has learned parrot fashion, and as like as not, to save himself a little trouble, includes it in the plumber's tender, (although why, now that the electrical trade is recognized as a distinct business, he does not just as reasonably include it in the plasterer's tender, can only be explained by the parrot theory). The contract is adjudged to the lowest tenderer, whether it be John Jones, who carries his office in his hat, and is here to-day and there to-morrow, or the None-Such Electrical Company of recognized ability and honesty—taxpayers, with an established place of business where they can always be found.

Does Mr. Citizen happen to be skeptical about Mr. Architect's knowledge, he is at once met by the latter triumphantly pointing to the clause that the wiring is "subject to Underwriters' rules" (parrot again). But Mr. Citizen has been posting himself and knows that the Underwriters have never been known to pay any attention to whether their rules were adhered to or not, and that so far as the insurance companies are concerned, this clause might as well read "subject to the rule of thumb." Again Mr. Architect is ready, and inserts another (parrot) clause, that a certificate of inspection will be demanded from the successful tenderer, said certificate to be paid for by the latter (not by insurance company), and the citizen feels that now indeed he has taken every precaution. Vain hope; false security! The initiated know that this certificate reads that "the work has been inspected and found free from grounds and short circuits, at time inspection was made," which is usually before plastering, the most fruitful season for both these evils, and does not cover grounds in wiring of fixtures not then put up. The job is finished, the contractor is paid and the citizen is left—to discover that he has either to do without his light or employ some on to put it in shape, whose account, added to the "lowest bidder's," makes the cost for this patched-up job more than if he had given it to the highest tenderer at first, and he does the inspector a grave injustice by including him in the blame which rightly should be saddled upon himself for sacrificing everything to price, and to the architect, for not advising him otherwise.

This condition of things can only be remedied by adopting the United States plan of putting safety before cost, and by either the city or insurance companies making certain rules compulsory, and seeing them enforced. As it is, an inspection certificate is optional, and is not a complete safeguard if received. A specification may call for rubber-covered wire, and the house be wired throughout under plaster, with cheap weather-proofing which only a man in the electrical business could distinguish, but which would be likely to cause a fire, and neither citizen nor architect be the wiser, by unscrupulous tenderers goaded on to low prices. I can point to houses in the city of Montreal to-day so wired.

Go into any supply house in our city and ask for dummy rosette, and you will get them; ask their use and you will be told they are merely a blind. Let me try to talk up the superior merit of some article to an architect and he will answer: "A socket is a socket," —without my daring to remind him (under the penalty of his everlasting wrath) that "an egg is an egg," but there are such things as rotten ones.

I fear I have already encroached too much upon your space for the present, but may take a future opportunity of further expressing my views on the subject.

Yours truly,

"WIREMAN."

Montreal, June 8, 1896.

A GREAT MOSAIC.

THE British Vice-Consul in Venice in his last report says that mosaics still continue in great demand there. The Venice and Murano Company executed last year a splendid mosaic for a palace now in course of construction in Vienna. It measures a thousand square feet, and is copied from cartoons by the painter Edward Weitk. It represents the five parts of the world. Murope stands in the centre of the frieze, represented by the symbolic figures of its various nations, having on one side the emblems of industry and trade, and at the top the emblem of the flying genius of light. On the right are Asia, India, China and Japan, with their rajahs, mandarines and the allegorical chrysanthemum. Next follows Africa, with camel drivers, palm trees and other African symbols; on the left, America and Australia, with natives on horseback and on foot, foliage and other emblems. All this variety of types, from the fair Circassian down to the negro, and the display of costumes from the most decorative to the simplest, have enabled the painter to arrange twenty-four figures with great delicacy of coal and in an artistic manner. Over these figures, which rest on an ornamental base, a blue sky reflects all around its light so as to unite all the tints of the mosaic, and to give the whole a harmony of effect which is said to be most delightful to the eye. The same company is executing another important mosiac for the apse of the Guards' Chapel at the Wellington Barracks, in London, from cartoons painted by Messrs. Clayton & Bell.—London Times.

At the Master Plumbers' session recently held at Cleveland, the Executive Committee was instructed to aid the master plumbers of Canada to organize their Dominion Association.

The roof pitch of forty-five degrees from the horizontal, leaving ninety degrees at the ridge, is not too flat for head-room nor to shed rain and snow. Roofs should as far as possible have one predominating pitch over all the house.

An interesting little brochure relating to the use of Cabot's Sheathing and Deafening Quilt in sound-proof construction, has reached our table. This "quilt" consists of fettled matting of eel-grass, held in place between two layers of strong manilla paper by quilting. Mr. Samuel Cabot, Boston, Mass., is the manufacturer.

ARCH AND VAULT TESTS OF THE AUSTRIAN SOCIETY OF ENGINEERS AND ARCHITECTS.*

DURING the years 1891 and 1892 the Austrian Society of Engineers and Architects conducted a series of tests on brick and concrete arches and vaults that were in every way much more complete than any hitherto attempted. The results obtained have attracted much attention from engineers and architects, although the arches tested are not in general use in this country.

Some idea of the scale on which these tests were conducted may be gained from the statement of the contributions of money,

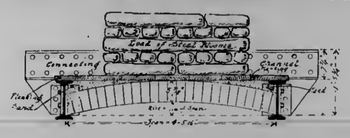

FIG. 1.—SECTION OF BRICK ARCH.

materials and labor from Government departments, railroads, manufacturing companies and private concerns, the total contributions from these sources amounting to $19,800.

The report covers (1) tests of eighteen floor arches, representing eight different types of floor construction; (2) tests of two culverts of 32.8 feet span and 1 in 10 rise; (3) tests of four bridges of 75 feet span and 1 in 5 rise; (4) an exhaustive series of tests to determine the strength and elasticity of all materials used in the above arches; (5) a theoretical calculation based on the results attained; (6) conclusion from the results in regard to theory and construction.

The object of the society in printing the report for general circulation is to bring about desired improvements.

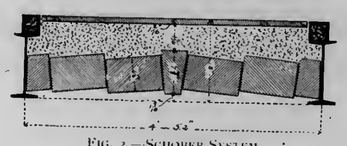

FIG. 2.—SCHOBER SYSTEM.

Of the various tests made those on the flat arches for floor construction will probably prove of most interest to architects. These tests include four arches of ordinary brick, five of flat tiles

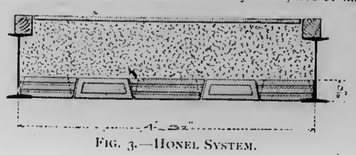

FIG. 3.—HONEL SYSTEM.

(differing entirely from those used in this country), three of concrete, three according to the Monier system, two of corrugated iron and one arch constructed according to the system Melan.

The above tests were divided into three series: A, seven arches with a span of 4 feet 5.16 inches; B, seven arches with a span of 8 feet 10.2 inches; C, four arches having a span of 13 feet 3.6 inches.

The arches in the first and second series were built between I-beams, which were rigidly secured and supported, so that no possible movement could take place. The third series was built between solid masonry abutments, as shown in Fig. 6.

This latter series of arches were regarded as a connecting link

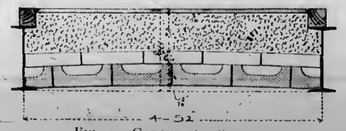

FIG. 4.—GLUCKSELIG SYSTEM.

between floor arches of small span and those of highway bridges, and the tests were instituted principally for making a comparison between arches of concrete, those of the Monier system and of brickwork. The tests of the flat arch systems were for spans of 4 feet 5.2 inches only, as these arches are not designed for much greater spans.

The construction of these arches is shown in Figs. 2 to 5.

Of the seven arches in the short-span series two were of brick (one header, one stretcher), one of concrete and one of each of the systems shown in Figs. 2-5.

The two brick arches laid up in white lime mortar showed practically no change under a load of 1,436 pounds per square foot.

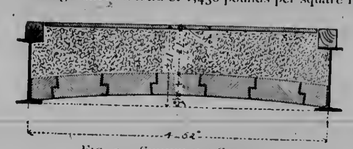

FIG. 5.—SCHNEIDER SYSTEM.

Of the ways of laying the bricks—headers or stretchers—the latter in every case showed a superiority, probably on account of the lesser number of joints.

The concrete arch, which was only 2 15/16 inches thick, with a rise of 4½ inches, was composed of one part Portland cement and five parts sand, and sustained 1,638 pounds per square foot without failure or cracking. The deflections of the concrete were about an average of the two brick arches, hence this arch may be considered as equal in strength to a brick arch 5⅞ inches thick, while it has the advantage of lesser weight.

The four flat arches showed an unexpectedly high carrying capacity.

The Schober arch (Fig. 2) and the Honel arch (Fig. 3) gave evidence of a very small deflection, even less than that of the brick arches, and a load of 1,638 pounds per square foot caused them to undergo very little change.

The Gluckselig arch (Fig. 4) failed under 1,638 pounds per square foot, and the Schneider arch (Fig. 5) under 1,651 pounds per square foot, both arches showing considerable deflection beforehand.

It may therefore be concluded that these arches are completely safe for all practical purposes, provided the skewback beams are not placed too far apart and the workmanship is first-class.

When using either of these systems, however, one must not be too economical in the use of tie-rods, to prevent any lateral deflection of the floor beams.

All of the above arches were tested by loading with iron and steel blooms. To get as uniform a load as possible a layer of cinders, etc., was evenly distributed over the arch and a planking composed of floor boards was placed thereon. The load was applied over the whole surface, and the arch had at least four months to set before testing.

SECOND SERIES.—This series consisted of one concrete arch 3⅜ inches thick; one arch of ordinary bricks, one arch of Honel's bricks, two Monier arches (one leveled up with cinders, the other with concrete) and two arches of corrugated iron, one with the edges reinforced and the other without reinforcements.

All were spring between I-beams placed 8 feet 10.2 inches apart between the webs.

Each of these arches was loaded over one-half of the arch only, although the arches were leveled up and the planking laid over the whole surface as in the first series.

The arch composed of ordinary bricks gave evidence of but little change under a load of 410 pounds per square foot, and carried 885 pounds per square foot before it failed. This arch was 5 5/16 inches thick, composed of a single course of brick, and had a rise of 9.85 inches.

To see if a thinner arch would answer the same purpose, one arch was constructed of "Honel's" bricks, which were only 3 15/16 inches thick, with a rise of 5 5/16 inches (1 in 20). This arch, however, failed under an eccentric load of 491 pounds per square foot, after having shown considerable deflection beforehand. It does not seem advisable, therefore, to use a 4-inch arch for so great a span.

The arch of concrete 3 5/16 inches thick, with a rise of 1 in 10, composition 1 to 4, fulfilled all requirements, as it sustained 614.4 pounds per square foot before it began to crack appreciably, and failed under an eccentric load of 1,130 pounds per square foot.

The two Monier arches deflected on an average equally as much as the concrete arch, and showed no appreciable superiority.

The arch leveled up with the concrete showed an increase in strength of only 8 per cent., although the superficial layer of concrete was applied immediately after the arch itself had been built.

The arches of corrugated iron deflected at the crown very much more than either the concrete and Monier arches.

The arch which had 2.3x2 3-inch angles riveted to the edges of the iron proved about 13 per cent. the stronger.

THIRD SERIES.—Span of 13 feet 3.6 inches.

The brick arch, 4⅞ inches thick, with a rise of 13¾ inches, commenced to crack under an eccentric load of 137.5 pounds per square foot, showing that it was much too weak for the purpose.

The concrete arch, 3 15/16 inches thick, with a rise of 15⅞ inches, failed under an eccentric load of 812 pounds per square foot.

The Monier arch, 2 inches thick, with a rise of 15½ inches, failed under an eccentric load of 895 pounds per square foot. The deflections of this arch were somewhat greater than those of the concrete arch.

After the above arches had been tested a new system appeared, the Melan patent, and an arch of this type being constructed by the manufacturers, it was tested in 1893 by the same committee.

This arch which had a span of 13 feet 11 inches and a rise of 11.4 inches, was constructed of curved ribs of 3½-inch I-beams, spaced 3 feet 3 inches apart, with 1 to 5 concrete rammed in between. The thickness of the arch was the same as that of the I-beams, 3½ inches. On account of the lack of material the loading of this arch was interrupted after 1,412 pounds per square foot, over one half of the arch, had been imposed. The

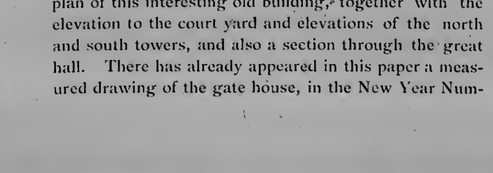

FIG. 6.—CONCRETE ARCH WITH MASONRY ABUTMENT.

permanent changes discovered after the removal of this load were very slight.

The report states: "From the behaviour of this construction there is no doubt that these vaults have a far superior carrying capacity than either the plain concrete or the Monier arch."

Aside from the great strength displayed by the Melan arch, which may be considered as a direct outcome of these tests, the most important fact developed is the superiority of the plain concrete arch, from a commercial point of view, over the Monier arch.

The ordinary Monier arch consists of wire netting imbedded in the concrete. To hold the netting the concrete must not be coarser than 1 to 3, which makes this system much more expensive than the plain concrete arch.

Referring to the two types of arches, the report says: "Compared with a plain concrete arch, a concrete arch with one wire netting has shown but little more carrying capacity, so that the difference cannot have any importance to the ordinary building practice."

Engineers have for a long time recommended Monier arches with two wire nettings for large spans, but it is nearly impossible to use two nettings in a small span.

In making all of the tests careful measurements were made of the deflection under different stages of loading, and these are given in the tables contained in the report.

* Report of the Committee on Arches and Vaults of the Austrian Society of Engineers and Architects. Special reprint from the Journal, Nos. 20-34. Vienna, 1895. (Printed in German.)

SHORING AND STRUTTING.—REPRODUCED FROM "THE BUILDER."

RESIDENCE, SPADINA ROAD, TORONTO.—CURRY, BAKER & CO., ARCHITECTS.

STOKESAY CASTLE.—MEASURED AND DRAWN BY EDWARD SWALES.

IN this number of the ARCHITECT AND BUILDER I give the ground plan and what we should call the first floor plan of this interesting old building, together with the elevation to the court yard and elevations of the north and south towers, and also a section through the great hall. There has already appeared in this paper a measured drawing of the gate house, in the New Year Number a sketch of the castle from the northwest corner, and in the May number a photographic reproduction of the Solar room.

The plans, I think, will be found interesting. Whether the founder of the house originally intended it for defence is not very apparent. The site at the foot of the hill would in these days be completely at the mercy of modern warfare. The gables and mullioned windows of the house are more suggestive of domestic life, and are so placed that attack would be easy from across the moat. The tower and moat bespeak a troubled time, when the owners found it expedient to strengthen their dwelling against their enemies. So we must consider it an early example of a moated dwelling rather than a castle or stronghold like its neighbor, Ludlow.

Little alteration seems to have taken place through the chances and changes that have levelled so many other similar buildings of that period; thus it has a special interest to the archaeologist. The moat was originally supplied from a pool which existed on the west side, and this by a small stream which ultimately flowed into the river Onny. Whether it was used to supply the moat to the original building is not easy to determine, and the depth cannot now be fixed. It is used as a garden and the ground is of different levels. A string course which runs round the hall and south tower is wanting round the northern one, and the masonry being also of a ruder description, indicating this to be the earliest portion of the structure. The batten on the base of this north tower and the depth of the foundations at this part, show that this portion was moated, a defence with which nearly all the earlier habitations were provided.

The gate-house replaces the original drawbridge, and the court yard was evidently surrounded by a strong parapet, pierced for cross-bows, of which the only remaining part is a few feet abutting on the south tower. Traces of foundations, probably of timber structures, which were usually built up to the parapet, can be traced near the north tower, and may have been used as stables, etc. On the opposite side stands the great hall, and at its southern end the Solar or withdrawing room, with the offices of the household. These would be the private apartments of the lord of the castle, and by the two squints his lordship could keep his eye on the retainers in the great hall below, which at night became the common dormitory for guests and servants. Then even in palaces the common sleeping place was a bench or the floor, which was covered with rushes; while a crib with a straw couch was probably the only furniture in a lady's bed-chamber. The priest and probably the principal guests were housed in the north tower. The south tower was intended as a last defence in case of siege, there being no indication of a drawbridge existing in place of the gangway. There is no doubt that it was always a temporary structure that could be easily destroyed. A covered way, probably of half timber, at one time led from the lower door to the Solar, as indicated by the string weathering under the window.

However picturesque these old buildings may look, the domestic arrangements must have been very draughty even in their best days. The well proportioned windows to the hall, mullioned and transomed with trefoils and circle, are excellent specimens of early English tracery, grooved in the upper parts for sashes, and in the lower, instead of grooves, holes sunk for iron bars, and supplied with shutters. Before the twelfth century glass was a

great luxury. Between the windows are three buttresses, which were found necessary to counteract the weight of the roof, which has thrown the walls out of perpendicular. These additions are considerably later, and marked new on plan.

On entering the hall you are at once struck by its proportions. The massive beams which support the roof are arched, springing from stone corbels on each side. The windows have stone seats, except the two northern ones, which are only half length, the one over the entrance being now built up, and the one at the end on the west side, which will be seen in the sketch published in January, has somehow lost its upper part, and horizontal beams of wood are inserted and now fitted with doors. There was the remains of some iron work, which by some authorities is supposed to have belonged to part of a drawbridge, but it is very unlikely that a drawbridge would communicate direct into the great hall. Some years ago it was used as a barn, and this doorway was made, in my opinion, at that time. There is no appearance at the upper end of any dais, for the small door at the end is on a level with the rest of the floor. Probably a temporary one was used. The hall has never been paved or tiled in any way, except nearly midway between the sides there is an octagonal pavement for the brazier—the only provision for a fire. There is no chimney. The beams of the roof above are blackened with the smoke of centuries. Everything in the place recalls the mediaeval baronial hall, and there still remain parts of heraldic devices that can be faintly traced in the now crumbling plaster.

The northern tower has been fully described in a previous number of this journal. The very narrow loopholes and rubble masonry show that it is the earliest portion remaining. In the lower chamber a well is sunk. Here again rude ornament can be traced on the walls.

Returning to the hall, a flight of solid oak steps lead to the chambers called the priests' rooms, and here is a collection of tiles, the "Centaur" and an "Archer with a Long Bow" being the more unusual patterns. An ogee window has been inserted in this room, and it may have been used as a chapel, although the church, which is quite as old as this tower, is close to the moat. At the southern end of the hall, through a square-headed trefoil doorway, characteristic of Edwardian architecture, into two small apartments, wainscoated and used as store-rooms, and an inner room terminating at the tower, steps lead into the only cellar. Well lighted by windows into the moat, above these rooms, and approached by the external stone steps already mentioned, is the handsome Solar. The tracery of the windows are similar to those of the hall, and are like them furnished with stone seats. In addition they are flanked with small lancets. On the court side the lancet window has been blocked up, and an ogee added, presumably to gain a better view of the gate-house. The two small squints with shutters at each side the fireplace, I have mentioned before. The remains of the elaborate panelling, and the magnificent chimney piece of oak of Charles II. time, still showing the color and guilding, with grotesque figures and scroll work, has even now an extremely rich effect. It rests on a massive grey stone arch. I hope to give a measured drawing of it at a future date. The inner chamber corresponding to the one below is provided with a wardrobe, and was the principal sleeping apartment.

Decending to the court an archway between the buttresses opens into the lower apartment of the south tower. In this is a large fireplace, and has no doubt been used as the kitchen. The principal entrance, however, is from the level of the Solar across the gangway, and in time of siege the lower doorway would be blocked up and the only approach destroyed.

The plan appears somewhat irregular, and the angles within and without do not correspond on examination, a good illustration of the carelessness of the old builders. It appears, as it were, two octagonal towers placed side by side, forming a rude heart shape. The walls are very thick in places (six feet). Each floor is provided with a fireplace, and for better defence the lancet windows on each floor command the different angles of the tower—each with a stone seat. A stair in the thickness of the wall leads from floor to floor, and in one room the decoration, consisting of a gray paint with flecks of brown, like whisps of hair, is still discernible.

The battlements on the roof consist of large embrasures, which originally had shutters, alternating with loop-holes for the use of cross-bows. A short flight of steps on the north side lead to a small watch tower over the stairs. The present owner has repaired the floors and put a good lead flat in place of the old roof which was burnt, and in many places repaired the walls, etc., keeping the whole in good order, but allowing nothing to be destroyed, and nothing is restored to death.

From the foregoing somewhat meagre description, it will be seen that Stokesay consists of three distinct parts. Of these the only portion of which any clear date of its erection can be fixed is the south tower. Any attempt to fix the order in which the others were built must rest on inferences drawn from the plan or the history of its owners. The castle now belongs to Mr. Allcroft, who keeps it in an excellent state of repair. The whole country from Liverpool to Hereford, through Shrewsbury and Ludlow, teams with interesting spots for the artist and archaeologist, and with historical associations—a splendid field for the architectural student visiting England. And the district is comparatively little known.

EDWARD SWALES.

ARTS AND CRAFTS ASSOCIATION.

THE Arts and Crafts Association of Hamilton opened its doors for the third annual exhibition on June 4th. Among the articles of interest was a carved mahogany piano stool by J. R. Seavey, which was a neat piece of workmanship. A. Lutes, an amateur, contributed a pedestal, surrounded at top and foot with oak leaves. P. L. Scriven's wood engravings were also creditable. Bell-Smith's Westminster and Port Neuf's pictures were models in architectural drawing.

Mr. and Mrs. Norris gave an exhibition of pottery-making, which was repeatedly applauded. R. Carroll, wood-carver, exhibited and worked on a panel a modern Italian renaissance, with cupids as central figures. It is a masterpiece of wood-carving, bringing out the cupids to good advantage.

Metal spinning and metal work were among the interesting features of the exhibition. The exhibition lasted ten days, and was creditable to the city of Hamilton.

The Kingston News says there is an opening for a cement works at Kingston, with plenty of material close at hand from which to make cement and pressed brick.

MR. KIVAS TULLY, C. E.

WE have the pleasure to present to our readers the accompanying portrait and particulars of the long and active career of Mr. Kivas Tully, C.E., who has recently retired from the active duties of the position of Chief Architect of the Public Works Department of Ontario.

Mr. Tully, second son of the late Commander John P. Tully, R. N., was born in Queen's County, Ireland, in 1820, educated at the Royal Naval School, Canterwell, London, England, and served his time as architect and civil engineer with the late W. H. Owen, architect and civil engineer, Limerick. After serving his time he was engaged in the erection of workhouses in Ireland, under Mr. Wilkinson, architect for the Poor Law Commissioners, having acted as inspector of buildings during the latter portion of 1843. In 1844 Mr. Tully emigrated to Canada and started business in Toronto as an architect and civil engineer. During 1845 the Custom House and Bank of Montreal on the corner of Front and Yonge streets, recently pulled down for the erection of the present structures, were constructed from his designs, after competition with other architects, and in 1848 the town hall and market building were erected by Mr. Tully, after competition. In 1850-51, Trinity College, Toronto, was erected by Mr. Tully, the

MR. KIVAS TULLY, C. E.

Welland County court house and jail in 1854-55, and the Victoria Hall, Cobourg, in 1857, after competition. In 1855-56-57 Mr. Tully, with Col. R. B. Mason, C.E., of Chicago, as consulting engineer, made the survey of the Toronto and Georgian Bay Ship Canal, and the report was published in 1858, the estimated cost being $22,170,000. In succession to the above the Ontario Ship Railway Company was granted a charter by the Ontario Legislature in 1892, for the construction of a railway to carry ships of 5,000 tons from Georgian Bay to some point on Lake Ontario, to cost $16,000. Mr. Tully was appointed chief engineer with E. L. Corthell, C.E., of Chicago, as consulting engineer, and Mr. David Blain, managing director.

In March, 1853, Mr. Tully was appointed engineer by the Toronto Harbor Commissioners, an office which he still holds with the consent of the Government. On the 22nd of March, 1856, the visiting commissioners of the Asylum for Insane, Toronto, appointed Mr. Tully architect to the asylum, which was afterwards confirmed by His Excellency, the Governor-General, and he has been enrolled as a civil servant since that time. Early in March, 1866, contracts were entered into for the erection of the wings and hospitals of the Asylum for Insane, Toronto, in accordance with his designs, Mr. Tully, by order of the visiting commissioners, having inspected several insane asylums in the United States in the autumn of 1865. The wings, etc., were completed and occupied in 1870—three years after Confederation. In January, 1868, Mr. Tully was transferred to the Department of Public Works, Ontario, the Hon. John Carling being the first Commissioner, and the building of the wings and hospitals was continued under the Commissioner of Public Works. The act organizing the department, which was prepared by Mr. Tully, was not passed until the 23rd of January, 1869. Under that act Mr. Tully was appointed architect and engineer and chief officer and performed the duties as such until 1874, when the act was amended appointing a separate engineer. At the change of Government in 1871, the Hon. Mr. McKellar was sworn in as Commissioner of Public Works, and acted as such until March, 1874, when the Hon. C. F. Fraser was sworn in as Commissioner, and he has continued to act until the present time, a period of upwards of twenty years.

From the year 1856 to the present time, a period of 40 years, the principal public buildings belonging to the province, representing an expenditure of about $7,000,000, were erected under his superintendence and directions.

Mr. Tully has also served the public as a member of the Board of Public School Trustees of Toronto from 1854 to 1858 inclusive.

GUILD OF SCULPTURE OF ONTARIO.

IN response to an invitation made by the Council of the above Guild, which has been formed for the encouragement and training in sculpture, and its allied crafts, a numerously attended meeting of representative artists and workers in the various branches of the plastic arts, including practitioners in marble, stone, wood, metals, art pottery and decorative plaster, was held on Friday last at the studio of Mr. Hamilton MacCarthy, R.C.A.

The object of the meeting was to organize an associate membership, and formulate the basis for holding the first exhibition of the combined plastic arts, which, it was decided to inaugurate in the fall. From the enthusiasm shown at the meeting the project promises every success, and from the well-known talents of the ladies and gentlemen, both professional and amateur, who have thrown themselves into the movement, public interest and advantage cannot fail to result when the exhibition takes place. Ontario has already become the home of many artists of the brush, whose works have done honor to the country, both at home and abroad, and some excellent public monuments, the work of Canadian sculptors, adorn a number of our Canadian cities, and it is of equal importance, not only from an artistic point of view, but also from a merchantile point of view, that both our sculptors and craft-workers should attain excellence in the subsidiary branches of the sculptors' art which go to affect architecture, decoration, design and manufactures.

In several branches of the sculptors' art Canada is still in its infancy; for instance, in metal work, in the goldsmiths' art, in which the Italians in the time of Cellini became so famous in the designing and chasing of trophies, racing cups, and other ornaments in metal.

The work of the hammer in iron, associated with the name of Guinton Matsys, we are glad to see has come into vogue, also the production and treatment of bronze, forming, perhaps, the most beautiful medium, as well as the most endurable material for the work of the sculptor.

In carving in stone our artists have attained much proficiency in Gothic and Romanesque, but little has been done in the human figure. Carving in wood is making some progress in ornament and low relief, yet as in stone much remains to be done in the higher branches.

There is also a field open for a Canadian art pottery. In Europe and the United States national schools of art pottery have been established with great success, and with the many fine clays we possess in this country, there is no reason why a Canadian faience should not come into repute both for home and export, and give employment for ladies and gentlemen of taste and skill. We may further mention the desirability of attaining excellence in designing and modelling of interior decorations in plaster of paris. Terra cotta is also one of the best materials for expressing the conceptions of the sculptor in the figure from the fact of the clay retaining the original impress and touch of the artist's handiwork.

The formation of a society, having for its object the cultivation, training, and encouragement of the plastic arts exclusively, is not only a novelty, but will be an acquisition to our art cults, and we have no doubt, when the exhibition is held, it will be, not only interesting and instructive, but a revelation to the public.

Mr. L. R. O'Brien, R. C. A., an artist who has taken a lively interest in every branch of the fine arts, is president of the Guild, and the Council include several of our best known sculptors and architects.

The membership of the Guild contains a large number of prominent citizens who have taken an active interest in the success of the Guild. The associate members will be exclusively composed of practical art workers in some branch of sculpture. An art union in connection with the Guild has been formed, and two beautiful busts of Canadian heros, General Sir Isaac Brock and Tecumseh, have been prepared in terra cotta for distribution to subscribers, specimens of which may be seen at Messrs. Matthews Bros., Yonge street.

The Guild feels sure that the public may look forward to the coming exhibition with great interest.

C. A. & B. STUDENTS' COMPETITION.

SEVERAL drawings have been received in the Students' Competition for a cover design for the next New Year number of the CANADIAN ARCHITECT AND BUILDER, but there has not been time for the judges to make their report thereon. The result will be made known in our July number.

great luxury. Between the windows are three buttresses, which were found necessary to counteract the weight of the roof, which has thrown the walls out of perpendicular. These additions are considerably later, and marked new on plan.

On entering the hall you are at once struck by its proportions. The massive beams which support the roof are arched, springing from stone corbels on each side. The windows have stone seats, except the two northern ones, which are only half length, the one over the entrance being now built up, and the one at the end on the west side, which will be seen in the sketch published in January, has somehow lost its upper part, and horizontal beams of wood are inserted and now fitted with doors. There was the remains of some iron work, which by some authorities is supposed to have belonged to part of a drawbridge, but it is very unlikely that a drawbridge would communicate direct into the great hall. Some years ago it was used as a barn, and this doorway was made, in my opinion, at that time. There is no appearance at the upper end of any dais, for the small door at the end is on a level with the rest of the floor. Probably a temporary one was used. The hall has never been paved or tiled in any way, except nearly midway between the sides there is an octagonal pavement for the brazier—the only provision for a fire. There is no chimney. The beams of the roof above are blackened with the smoke of centuries. Everything in the place recalls the mediaeval baronial hall, and there still remain parts of heraldic devices that can be faintly traced in the now crumbling plaster.

The northern tower has been fully described in a previous number of this journal. The very narrow loop-holes and rubble masonry show that it is the earliest portion remaining. In the lower chamber a well is sunk. Here again rude ornament can be traced on the walls.

Returning to the hall, a flight of solid oak steps lead to the chambers called the priests' rooms, and here is a collection of tiles, the "Centaur" and an "Archer with a Long Bow" being the more unusual patterns. An ogee window has been inserted in this room, and it may have been used as a chapel, although the church, which is quite as old as this tower, is close to the moat. At the southern end of the hall, through a square-headed trefoil doorway, characteristic of Edwardian architecture, into two small apartments, wainscoated and used as store-rooms, and an inner room terminating at the tower, steps lead into the only cellar. Well lighted by windows into the moat, above these rooms, and approached by the external stone steps already mentioned, is the handsome Solar. The tracery of the windows are similar to those of the hall, and are like them furnished with stone seats. In addition they are flanked with small lancets. On the court side the lancet window has been blocked up, and an ogee added, presumably to gain a better view of the gate-house. The two small squints with shutters at each side the fireplace, I have mentioned before. The remains of the elaborate panelling, and the magnificent chimney piece of oak of Charles II. time, still showing the color and guilding, with grotesque figures and scroll work, has even now an extremely rich effect. It rests on a massive grey stone arch. I hope to give a measured drawing of it at a future date. The inner chamber corresponding to the one below is provided with a wardrobe, and was the principal sleeping apartment.

Decending to the court an archway between the buttresses opens into the lower apartment of the south tower. In this is a large fireplace, and has no doubt been used as the kitchen. The principal entrance, however, is from the level of the Solar across the gangway, and in time of siege the lower doorway would be blocked up and the only approach destroyed.

The plan appears somewhat irregular, and the angles within and without do not correspond on examination, a good illustration of the carelessness of the old builders. It appears, as it were, two octagonal towers placed side by side, forming a rude heart shape. The walls are very thick in places (six feet). Each floor is provided with a fireplace, and for better defence the lancet windows on each floor command the different angles of the tower—each with a stone seat. A stair in the thickness of the wall leads from floor to floor, and in one room the decoration, consisting of a gray paint with flecks of brown, like whisps of hair, is still discernible.

The battlements on the roof consist of large embrasures, which originally had shutters, alternating with loop-holes for the use of cross-bows. A short flight of steps on the north side lead to a small watch tower over the stairs. The present owner has repaired the floors and put a good lead flat in place of the old roof which was burnt, and in many places repaired the walls, etc., keeping the whole in good order, but allowing nothing to be destroyed, and nothing is restored to death.

From the foregoing somewhat meagre description, it will be seen that Stokesay consists of three distinct parts. Of these the only portion of which any clear date of its erection can be fixed is the south tower. Any attempt to fix the order in which the others were built must rest on inferences drawn from the plan or the history of its owners. The castle now belongs to Mr. Allcroft, who keeps it in an excellent state of repair. The whole country from Liverpool to Hereford, through Shrewsbury and Ludlow, teams with interesting spots for the artist and archaeologist, and with historical associations—a splendid field for the architectural student visiting England. And the district is comparatively little known.

EDWARD SWALES.

ARTS AND CRAFTS ASSOCIATION.

THE Arts and Crafts Association of Hamilton opened its doors for the third annual exhibition on June 4th. Among the articles of interest was a carved mahogany piano stool by J. R. Seavey, which was a neat piece of workmanship. A. Lutes, an amateur, contributed a pedestal, surrounded at top and foot with oak leaves. P. L. Scriven's wood-engravings were also creditable. Bell-Smith's Westminster and Port Neuf's pictures were models in architectural drawing.

Mr. and Mrs. Norris gave an exhibition of pottery-making, which was repeatedly applauded. R. Carroll, wood-carver, exhibited and worked on a panel a modern Italian renaissance, with cupids as central figures. It is a masterpiece of wood-carving, bringing out the cupids to good advantage.

Metal spinning and metal work were among the interesting features of the exhibition. The exhibition lasted ten days, and was creditable to the city of Hamilton.

The Kingston News says there is an opening for a cement works at Kingston, with plenty of material close at hand from which to make cement and pressed brick.

MR. KIVAS TULLY, C. E.

WE have the pleasure to present to our readers the accompanying portrait and particulars of the long and active career of Mr. Kivas Tully, C.E., who has recently retired from the active duties of the position of Chief Architect of the Public Works Department of Ontario.

Mr. Tully, second son of the late Commander John P. Tully, R. N., was born in Queen's County, Ireland, in 1820, educated at the Royal Naval School, Canterwell, London, England, and served his time as architect and civil engineer with the late W. H. Owen, architect and civil engineer, Limerick. After serving his time he was engaged in the erection of workhouses in Ireland, under Mr. Wilkinson, architect for the Poor Law Commissioners, having acted as inspector of buildings during the latter portion of 1843. In 1844 Mr. Tully emigrated to Canada and started business in Toronto as an architect and civil engineer. During 1845 the Custom House and Bank of Montreal on the corner of Front and Yonge streets, recently pulled down for the erection of the present structures, were constructed from his designs, after competition with other architects, and in 1848 the town hall and market building were erected by Mr. Tully, after competition. In 1850-51, Trinity College, Toronto, was erected by Mr. Tully, the

MR. KIVAS TULLY, C. E.

Welland County court house and jail in 1854-55, and the Victoria Hall, Cobourg, in 1857, after competition. In 1855-56-57 Mr. Tully, with Col. R. B. Mason, C.E., of Chicago, as consulting engineer, made the survey of the Toronto and Georgian Bay Ship Canal, and the report was published in 1858, the estimated cost being $22,170,000. In succession to the above the Ontario Ship Railway Company was granted a charter by the Ontario Legislature in 1892, for the construction of a railway to carry ships of 5,000 tons from Georgian Bay to some point on Lake Ontario, to cost $16,000. Mr. Tully was appointed chief engineer with E. L. Corthell, C.E., of Chicago, as consulting engineer, and Mr. David Blain, managing director.

In March, 1853, Mr. Tully was appointed engineer by the Toronto Harbor Commissioners, an office which he still holds with the consent of the Government. On the 22nd of March, 1856, the visiting commissioners of the Asylum for Insane, Toronto, appointed Mr. Tully architect to the asylum, which was afterwards confirmed by His Excellency, the Governor-General, and he has been enrolled as a civil servant since that time. Early in March, 1866, contracts were entered into for the erection of the wings and hospitals of the Asylum for Insane, Toronto, in accordance with his designs, Mr. Tully, by order of the visiting commissioners, having inspected several insane asylums in the United States in the autumn of 1865. The wings, etc., were completed and occupied in 1870—three years after Confederation. In January, 1868, Mr. Tully was transferred to the Department of Public Works, Ontario, the Hon. John Carling being the first Commissioner, and the building of the wings and hospitals was continued under the Commissioner of Public Works. The act organizing the department, which was prepared by Mr. Tully, was not passed until the 23rd of January, 1869. Under that act Mr. Tully was appointed architect and engineer and chief officer and performed the duties as such until 1874, when the act was amended appointing a separate engineer. At the change of Government in 1871, the Hon. Mr. McKellar was sworn in as Commissioner of Public Works, and acted as such until March, 1874, when the Hon. C. F. Fraser was sworn in as Commissioner, and he has continued to act until the present time, a period of upwards of twenty years.

From the year 1856 to the present time, a period of 40 years, the principal public buildings belonging to the province, representing an expenditure of about $7,000,000, were erected under his superintendence and directions.

Mr. Tully has also served the public as a member of the Board of Public School Trustees of Toronto from 1854 to 1858 inclusive.

GUILD OF SCULPTURE OF ONTARIO.

IN response to an invitation made by the Council of the above Guild, which has been formed for the encouragement and training in sculpture, and its allied crafts, a numerously attended meeting of representative artists and workers in the various branches of the plastic arts, including practitioners in marble, stone, wood, metals, art pottery and decorative plaster, was held on Friday last at the studio of Mr. Hamilton MacCarthy, R.C.A.

The object of the meeting was to organize an associate membership, and formulate the basis for holding the first exhibition of the combined plastic arts, which, it was decided to inaugurate in the fall. From the enthusiasm shown at the meeting the project promises every success, and from the well-known talents of the ladies and gentlemen, both professional and amateur, who have thrown themselves into the movement, public interest and advantage cannot fail to result when the exhibition takes place. Ontario has already become the home of many artists of the brush, whose works have done honor to the country, both at home and abroad, and some excellent public monuments, the work of Canadian sculptors, adorn a number of our Canadian cities, and it is of equal importance, not only from an artistic point of view, but also from a merchantile point of view, that both our sculptors and craft-workers should attain excellence in the subsidiary branches of the sculptors' art which go to affect architecture, decoration, design and manufactures.

In several branches of the sculptors' art Canada is still in its infancy; for instance, in metal work, in the goldsmiths' art, in which the Italians in the time of Cellini became so famous in the designing and chasing of trophies, racing cups, and other ornaments in metal.

The work of the hammer in iron, associated with the name of Guinton Matsys, we are glad to see has come into vogue, also the production and treatment of bronze, forming, perhaps, the most beautiful medium, as well as the most endurable material for the work of the sculptor.

In carving in stone our artists have attained much proficiency in Gothic and Romanesque, but little has been done in the human figure. Carving in wood is making some progress in ornament and low relief, yet as in stone much remains to be done in the higher branches.

There is also a field open for a Canadian art pottery. In Europe and the United States national schools of art pottery have been established with great success, and with the many fine clays we possess in this country, there is no reason why a Canadian faience should not come into repute both for home and export, and give employment for ladies and gentlemen of taste and skill. We may further mention the desirability of attaining excellence in designing and modelling of interior decorations in plaster of paris. Terra cotta is also one of the best materials for expressing the conceptions of the sculptor in the figure from the fact of the clay retaining the original impress and touch of the artist's handiwork.

The formation of a society, having for its object the cultivation, training, and encouragement of the plastic arts exclusively, is not only a novelty, but will be an acquisition to our art cults, and we have no doubt, when the exhibition is held, it will be, not only interesting and instructive, but a revelation to the public.

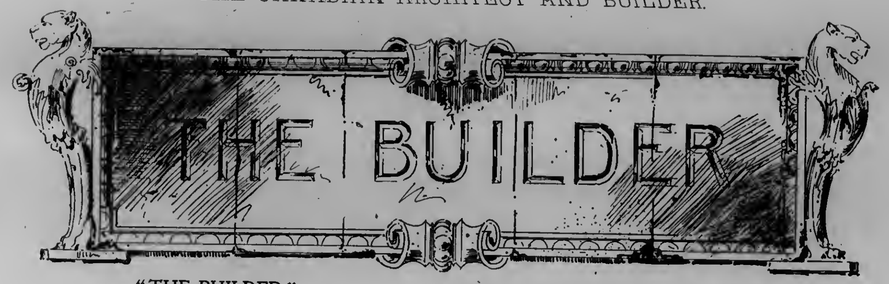
Mr. L. R. O'Brien, R. C. A., an artist who has taken a lively interest in every branch of the fine arts, is president of the Guild, and the Council include several of our best known sculptors and architects.

The membership of the Guild contains a large number of prominent citizens who have taken an active interest in the success of the Guild. The associate members will be exclusively composed of practical art workers in some branch of sculpture. An art union in connection with the Guild has been formed, and two beautiful busts of Canadian heros, General Sir Isaac Brock and Tecumseh, have been prepared in terra cotta for distribution to subscribers, specimens of which may be seen at Messrs. Matthews Bros., Yonge street.

The Guild feels sure that the public may look forward to the coming exhibition with great interest.

C. A. & B. STUDENTS' COMPETITION.

SEVERAL drawings have been received in the Students' Competition for a cover design for the next New Year number of the CANADIAN ARCHITECT AND BUILDER, but there has not been time for the judges to make their report thereon. The result will be made known in our July number.



"THE BUILDER."

We have occasionally been met with the complaint on the part of contractors in the building trades that the Canadian Architect and Builder contained too little information adapted to the requirements of the master builder and contractor. Recognizing the justice in some measure of this complaint, the size of the journal has with the present number been increased to an extent sufficient to admit of the establishing of this department and the publication therein of a large amount of matter suited to the needs of contractors in the various trades as well as of the country builder who requires to be possessed of some knowledge of every department of building work.

Contractors are invited to ask through this department tor any required information which they do not find appearing therein, when every effort will be made to supply it. They are also requested to contribute through this department for the general benefit, anything of value on the line of improved methods of carrying out work, the nature and use of materials, etc. Country builders who have not the same opportunity as their city brethren of becoming acquainted with new materials and methods, should not hesitate to avail themselves of the privilege of asking questions.

If those for whose benefit this department has been especially provided will assist in promoting a free interchange of ideas and experiences on the line of their every-day work, a great deal of helpful information will be the outcome.

BUILDING AND SANITARY CONSTRUCTION.

The following extracts are taken from a lecture on the above subject to students and clerks of works at Carpenters' Hall, London, Eng., by Professor Banister Fletcher, professor of architecture at King's College:

We call it sanitary building. Why might we not call it, as our forefathers did, simply good, sound building? The first subject is bricks. Nearly all buildings are of brick, or of brick faced with stone.

The essential qualities of a good brick are hardness, not absorbing more than one-sixth its weight of water, well burnt, free from flaws, having a good ring when struck, the surfaces level, neither hollow nor round, except the frog, and the surfaces not too smooth, or the mortar will not adhere. A very highly vitrified brick will only absorb from one-thirteenth to one sixteenth its own weight. The softer stock brick will absorb 1 lb. 1 oz. of water; the harder brick about 9 oz. It must be remembered this result is obtained when we have all the surfaces exposed to the water by immersion in a pail for twenty-four hours. In a recent case it was contended by council that a brick in a building absorbed the same quantity as it did when thus immersed—a strong example of the weakness of theory without practice. A practical man knows that only one face is exposed to the weather; if it is a stretcher, then we have only one-fifth of the entire surface exposed, and if a header then still less by one-half. The wall in question had a dust-bin outside, and, it was alleged, was too damp for habitation. As a practical test a brick was taken out just behind the skirting; the painting of the skirting was not injured or blistered in any way, as it would naturally be by the action of damp, and the brick behind was perfectly dry. I cite this to show that theory requires a knowledge of practise to make it of value. An imperfectly burnt brick must be bad because it becomes sodden with water and is easily damaged by frost; it causes also the wall to be cold and damp. If chalk is present imperfectly ground, the brick is liable to serious flakings. The burning turns the chalk into lime, water reaches it, and the brick is blown, or disintegrated, by the action of the water on the lime. The frog gives a key for the mortar, and keeps the brick in position.

Stone.—Durability is the most important item. The most powerful agencies in the destruction of stone are nitric acid, carbonic acid, and the moisture of the atmosphere. Stone in the country ought practically to stand for ever. But in towns it is exposed to the influences of sulphur and hydrochloric acid. Carbonic acid and water causes a great amount of decomposition. The use of porous stone should be specially avoided in facades exposed to the south, south-west or west winds, because from these quarters we get the driving wind and rain. The decomposing gases in the air are driven further in by the rain. Frost increases the bulk of the water and blows out the stone. One way of testing stone is to weigh when dry and after immersion in water, in the same way as the test for brick already mentioned. If you find that the stone does not absorb half a gallon per cubic foot, you may consider it a good building stone. Another test is that of two stones having similar qualities; that which has the greatest density or specific gravity is the best.

Some of you hereafter may probably be sent down to examine stone at a quarry. To assist you in deciding on the merits of the stone, examine the old buildings in the neigborhood; the tool-marks should still show on a good stone. Finding the stone in the old building good is not in itself satisfactory. It is necessary further to inquire about the bed from which the stone was quarried; it may be the bed is exhausted, and beds of stone in the same quarry differ very much. See also that your stone is seasoned. Wren, during the building of St. Paul's, would have no stone used that had not been quarried for three years. The result of this care is that no stone shows signs of decay. A further proof of the necessity of thus getting stone free from sap was given by a recent experience with St. Martin's-in-the-Fields. A portion of the stonework was decaying, and an examination brought out the curious fact that the whole of the faulty stones were stones that had been put there some twenty years before. At that time the mason had ascertained what stones were required, sent off the sizes to the quarry, and with the desire to get the scaffold down the stones had been put in full of quarry sap. The result was that they required renewal in twenty years. This term quarry sap is one that some people are startled at, but it is really no more than the natural sap in timber. It is simply water in the stone and a normal condition for all stone while in its natural bed. You may see when travelling in the west of England large quantities of stone drying where the quarries are near the railway. It is a rule at most quarries to send no stone to London from which the quarry sap has not been dried out. It is sometimes found more economical to have the stone cut and moulded at the quarry, because of the labor being cheaper. Against this has to be set the liability to damage in transit.

Timber should be got from the heart of a sound tree. The sap should be removed; it should be uniform in substance, free from large or dead knots or blemishes, sonorous when struck; the annular rings should be regular in form and color; the dust when freshly cut should smell sweet; the surface should not be woolly in texture nor clog the teeth of the saw, and it should be firm and bright with a silky texture when planed. A wood having a disagreeable smell and a dull chalky appearance, and which gives out a heavy sound when struck, is not a good wood. To mature wood it must be kept constantly dry and free from the influence of damp walls or damp earth. Remember, however good your timber may be, that the best can be destroyed. Allow air to pass all round it; it should be utterly free from resting on walls; all wall timbers should rest on corbels. If your timber does decay there is then no disturbance of the walls.

Mortar, Limes and Cement.—You cannot have sanitary building if the mortar is bad. With bad mortar you get open and decaying joints, and water is allowed to pass through. It has been alleged that bad building is peculiarly a modern achievement, but it may be a cheering refutation of this to be reminded that very early in the Christian era Virtuvius was complaining of bad building.

Mortar is used to bind bricks or stones together, and to give an even bed. We have in ancient buildings, notably in Greek work, some fine examples where no cementing material is used. The stones are large and so nicely fitted that none is needed.

What is our mortar to be composed of? Well-slacked lime and clean sharp sand in the proportion of one to three. The sand must be free from salt; salt attracts and holds water, and if present in the mortar, water would pass from the outer to the inner surface, and you cannot keep it back.

Where you have to build in damp and wet soils, no doubt Portland cement is the best to use. Roman cement sets quicker, but has not the same power of sustaining weight.

Bond.—English bond should always be used unless you want prettiness of effect. English bond is alternate courses of headers and stretchers, and is invariably used for warehouses and all structures where strength is necessary. Bond is of the utmost importance. The lowest course must be properly laid. The first course governs the whole building, even if it is 80 feet high. Bond is a breaking of joint on the face of the wall and in the thickness of the wall throughout. We break it by a smaller brick called a closer. Never put closer next stretcher; always put it next to header; the smaller size of the closer is not then so prominent.

Flemish bond is alternate header and stretcher, and is certainly prettier, but it is not so strong, and it lends itself to the abominable practice of using bats, which are not always half-bricks, but any part of a brick.

Bricks must be of such a size that two headers, with the joint, equal one stretcher. It sometimes occurs on a building that bricks become short; you may be sent to the center brick-fields to obtain more. If so, it is well to take one of the bricks used on the building with you, otherwise you may not get them exactly the same size, and your building may show an unpleasant break in its lines which will always be a source of worry. Take three bricks; lay one as stretcher; then see if two laid as headers just leave room for the mortar joint.

A perfect wall should be so thick as to prevent damp penetrating. Dampness may arise from the bottom. This is prevented by a damp-course. Various methods are employed—asphalt, tar and lime, slate, or hollow stoneware blocks. Asphalt is best. In the event of a settlement it is not easily broken.

Damp from above is prevented by brick on edge or in the form of a ridge, or in what is known as the saddle-back form (the best), or by a plain stone covering or a stone having a feather edge. Damp is prevented from passing through in some cases by means of hollow walls. It does not matter what quantity of water goes into the outer wall as long as you keep it from the inner. It is necessary to provide means for carrying off water at the bottom of the hollow part of a wall and ventilating openings at the top. Formerly the inner portion of a wall might be of less thickness; now the law requires the inner portion of a wall must be the same thickness as if there were no outer wall forming with it a hollow wall. This makes it improbable that many will use it. As an alternative, 1 inch of asphalt can be put against the wall.

After referring to diagram showing the pitch generally used for the various roofing materials and referring the students to the by-laws on plasterer's work, the lecturer said a roof is best described by a bow and a string. The tie beam is the string: the timbers form the bow. Set your lines out within this form. It is a mistake to think it is held up by the king post. The roof is really held up by the tie beam.

Lastly, in all construction, if you have two methods given you, take that which has the simplest parts. Test for yourselves everything you hear. Never rashly adopt new inventions. A new invention probably solves one special need, and in doing so gives you several others to solve. Take as example the old wash-out closet. Every sanitary authority praised and recommended it. Now, it is not permitted anywhere.

TORONTO BUILDERS' EXCHANGE.

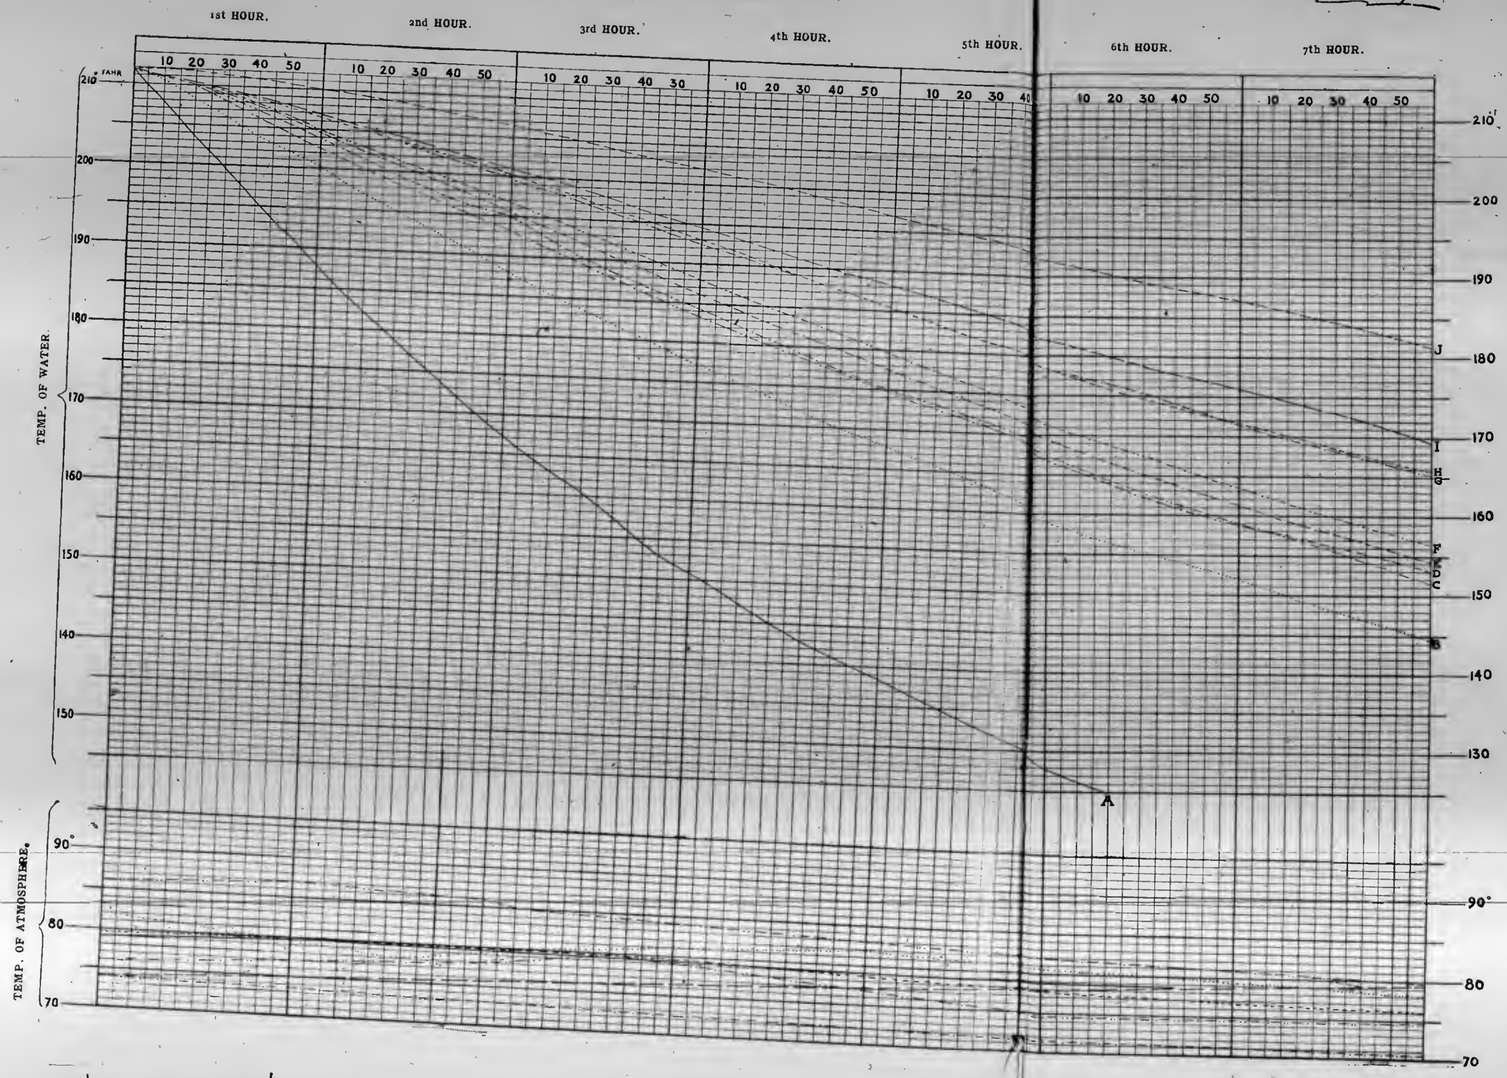
The annual excursion of the members of the Toronto Builders' Exchange and their friends will take place, as usual, to Wilson Park, N. Y., per steamer Tymon, on the 11th of July. This excursion has in past years proven to be a most enjoyable one, and, if the weather should prove favorable, those who may take part in the event this year are assured of a pleasant outing. As usual, an attractive list of athletic sports will be a feature of the programme.

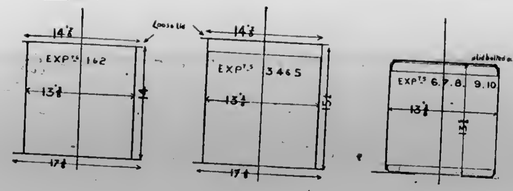
CANADIAN PACIFIC RAILWAY

MECHANICAL DEPARTMENT

DIAGRAM OF EXPERIMENTS WITH BOILER COVERINGS.

(Reproduced from Canadian Pacific Railway Company's Chart.)





The order in which the experiments were made, and the materials tested were as follows :—

1st Expt. Tank uncovered.....

2nd " " with air-space of ⅞ in. next tank, wood lagging ⅜ in. thick, and outer coat of Russian iron ..... H

3rd " " same as in 2nd Expt., but with Asbestos woven cloth ¼ in. thick, inserted in the ⅞ in. space, and placed next tank..... I

4th " " covered with Plastic Asbestos Compound, and outer coat Russian iron Comp. 1½ in. thick ..... J

5th " " covered with Sectional Magnesia Blocks, and outer coat Russian iron Comp. 1½ in. thick ..... G

6th Expt. Tank covered with Patent Mineral Composition, and outer coat Russian iron Comp. 1½ in. thick..... C

EXPERIMENTS WITH BOILER COVERINGS.

The accompanying chart is a reproduction of a diagram of experiments with boiler coverings made by the Canadian Pacific Railway Co. to test the values of various compounds as non-conductors of heat.

It will be seen that water at 212° was used, the relative value of the coverings as non-conductors being determined by the number of degrees of heat which escaped through the different substances and the consequent cooling of the water in a given time. A reference to the chart shows that ten experiments were made. It will not be necessary, however, to refer to all of them, as the results of some were so unimportant, as in experiments 4, 6 and 9, as to render them of little interest or value. It is only necessary to say that the trials were made under as nearly similar conditions as possible, as will be seen by the diagram of the atmospheric temperatures during the tests. The readings were taken from thermometers passed through the coverings and down into the body of the water.

The chart shows the loss of heat in the uncovered tank up to the 5th hour only, and to make a fair comparison the others should be taken for same time. The temperature at beginning of each test was 212°, and the following table shows the temperature at end of fifth hour, the loss in five hours, and the loss in the fifth hour :—

	Loss in 5 hours.	Temp. at end of 5th hour.	Loss in 5th hour
Bare tank	84°	128°	11°
Asbestos compound	53°	159°	9°
Sectional magnesia blocks	33¾	178¼	7°
Wood lagging and air space	"	"	"
Asbestos and wood	30°	182°	6°
Mica	20°	192°	5°

The mean temperature of the surrounding atmosphere during the 5th hour may be taken as having been 78°.

The fairest comparison of the merits of the coverings is made by considering the loss of heat in one hour per degree of difference of temperature between the tank and its surrounding atmosphere.

The following table shows this worked out :—

	Mean temp. during 5th hour.	Difference between tank and atmosphere.	Loss in 5th hour.	Loss in 5th hour per degree of difference of temperature.
Bare tank	133½°	55½°	11°	.198
Asbestos comp	103½°	85½°	9°	.105
Sectional Magnesia blocks	181¼	103¾°	7	.0674
Wood lagging and air space	181¼	103¾	7	.0674
Asbestos and wood	185	107	6	.056
Mica	194½°	116½°	5°	.0428

The following table shows the value of the coverings as compared with the bare tank.

Amount of heat which escapes from the bare tank was
1.88 times greater than through the Asbestos compound.
2.92 " " " " " Sectional Magnesia Blocks.
2.92 " " " " " Wood lagging and air space.
3.53 " " " " " Asbestos and wood.
4.62 " " " " " Mica.

Mica shows by far the best result as a non-conductor of heat, and saved
245 per cent as much heat as the Asbestos compound.
157 " " " " Sectional Magnesia blocks.
157 " " " " Wood lagging and air space.
139 " " " " Asbestos and wood.

It will be seen from the diagram that the loss by radiation through "sectional magnesia blocks" and "wood and air space" was practically the same, there being less than ½° Fht. between them at the expiration of the test.

It will be seen that asbestos cement, which is in very

general use, particularly on marine boilers, showed infinitely the worst results. There seems no room for doubt that this is largely attributable to the fact that it is a solid composition, and lacks one of the most vital requirements of successful non-conductivity, i. e., "diffused air." That the air must be diffused or separated into minute cells is strikingly illustrated in experiments 2 and 3. In the first, wood and air space of ⅞ inch next to the tank, as used on locomotive boilers, the loss per degree of difference of temperature was .0674°. When the same air space was filled or packed with asbestos fibre the loss dropped to .056°. In the case of mica, the air theory appears to have been carried to the furthest possible extent, the whole covering forming a veritable air cushion, each leaf or film of mica being separated from the next by minute corrugations, the whole mat presenting the appearance of a porous flexible quilt. The value of this ingenious arrangement was amply proved in the experiments in question, when the loss per degree in difference of temperature was only .0428°. That this is one of the most important qualities of a covering has long been recognized, and a large number of patents have been granted for devices intended to obtain it. But in nearly every instance it has been at the expense of the material. The great differences in the value of the coverings tested by the C.P.R. is due largely to the manner in which the valuable properties of diffused air as a non-conductor have been utilized.

The following table will give some idea of what the loss of power has been found to be from uncovered steam-pipes with the steam at 75 lb. gauge pressure: —

2 inch pipe	.	1	horse power loss for every	132	feet	long.	
4	"	1	"	"	"	75	"
6	"	1	"	"	"	46	"
8	"	1	"	"	"	40	"
12	"	1	"	"	"	26	"

About 90 per cent. of this waste is easily prevented by a proper covering of the pipes. When it is considered that this loss occurs at the comparatively low pressure of 75 lbs., it is apparent that with steam at 130 lbs. and 140 lbs. and higher, the loss becomes very serious, and the necessity for preventing as much of it as possible is a matter of urgent importance.

The accompanying diagram very clearly demonstrates what can be done in this direction by the use of various compositions, as it clearly shows the qualities and capabilities of each. It is possible that the question might arise as to whether the great differences between these substances would still be found had the trials of the C. P. R. Company been made with higher temperature than 212°.

It appears, however, from published reports of trials made some months ago by the engineers of the Boiler Inspection and Insurance Company of Canada that these differences did exist; that company subsequently issued a special circular on the whole matter, as one of particular interest to steam users. It is stated further that the Grand Trunk Railway Company have lately concluded a series of trials, on a large scale and under high steam pressure, of a number of boiler coverings, including the best of those tested by the C.P.R. and the Boiler Inspection Company, the difference between them being even more marked. As no data, however, is as yet available of these trials, it is impossible to speak of them with accuracy. It is encouraging to notice the increasing attention the whole subject is receiving, in view of the imperative necessity for observing the strictest economy in power and coal and the prevention of all unnecessary waste.

CONCRETE FLOORS.

The most complete set of experiments upon the transverse strength of concrete, writes Mr. Geo. H. Blagrove in the Contract Journal, appear to be those of Mr. A. Fairlie Bruce, previously referred to. Mr. Bruce used bars 30 in. long by 4 in. square, broken by central pressure over a 27 in. span, and after some 300 tests he sought to obtain a modulus of rupture, f, by which the transverse resistance of concrete bars or slabs might be calculated. This modulus is to be used in connection with the ordinary formulæ, so that if d = the depth of the bar or slab, I = the moment of inertia, and M = the moment of resistance, then $M = \frac{2f}{d} I$.

The proportions of ingredients used varied from 5 to 1 to 12 to 1, and the age of the concrete varied from one week to half a year. Excluding instances where the materials were known to be defective, a few examples of the value of f may be cited. With 3 parts of broken sandstone and 2 parts crushed fine instead of sand to 1 of cement, we have f = 95 at one week, and 222 at four weeks. With the same proportions, but with red sandstone and pit sand, we have f = 30 at four weeks and only 228 at 39 weeks. Again, with 6 of sandstone and 2½ of pit sand to 1 of cement, we have f = 73 at four weeks; and generally with proportions of about 8 to 1 of cement, the value of f at four weeks varies from 57 to 166. These variations of strength cannot be directly traced to the nature of the materials used. For instance, with 5 of broken whinstone, 1 of the same crushed, and 2 of sandstone crushed—a total of 8 to 1 of cement—we have f = 58 at four weeks; and with 5 of the same aggregate and 2½ of crushed whinstone—a total of 7½ to 1—we find f = 166, or about 186 per cent. more. For purposes of comparison, Mr. Bruce calculated values of f from the results of Mr. Hutton's and Mr. Kyle's experiments. With proportions respectively of 8 and 9 to 1 of cement, we have f varying from 51·7 to 183·8 at 12 weeks, and from 102·2 to 316 at 20 weeks.

All Mr. Bruce's experiments show that there is a very great increase of strength with increased age, the value of f at one month being often doubled, and sometimes more than trebled, after six months. For examples of the transverse srength of concrete at greater ages, we would refer to experiments by Mr. Robert Moore, described in his paper on "Merchants' Bridge Terminal Railway."* Mr. Moore experimented with concrete composed with 6 parts of broken limestone and 3 of river sand to 1 of cement, made into bars 30 in. long and 9 in. square, buried for periods of eight, nine, ten, and eleven months respectively, and then dug up and broken by central pressure over a 27 in. span. The breaking weights varied from 6,030 lbs. to 8,030 lbs., and the values of f which we deduce from these results vary from 335 to 446.

Mr. Bruce has employed a formula for calculating the growth of strength in concrete, the data for which are of course deduced from experiments. Sometimes the calculated and observed values of f agree fairly well, but in many cases there are startling discrepancies. For instance, with concrete made with 5 parts of whinstone

* See Transactions Amer. Soc. C. E., vol. xxxi., 1894.

and 3 of pit sand, we have the calculated value of f at eight weeks = 104, and the observed value = 63; then with the same concrete we have the calculated value at 26 weeks = 141, and the observed value = 204. Such variations in results should suffice to shake our confidence in calculations of this kind.

PRACTICAL RULES FOR TRANSVERSE STRENGTH.

There is often some considerable difference between the quality of work specially prepared for purposes of experiment and that which is executed in large quantities with only a general supervision, which cannot take note of every possible source of weakness due to imperfections of workmanship. Bearing this in mind, it would be rash to assume that the degrees of strength revealed in the experiments to which we have referred can be expected to apply in general practice when the conditions are nominally the same. Two things must, therefore, be done in selecting values of f for practical use. First, the lowest values revealed in the experiments must be taken, because there is no certainty that the strength will rise above these in any given case. The custom followed by some writers of taking the average results of experiments is one that may lead to serious error. Next, a deduction must be made from these lowest values to allow for the difference in quality between ordinary work and samples made for testing.

It is probable that large slabs of concrete would show a higher proportionate degree of strength than the isolated bars used in the experiments, since these latter are devoid of that lateral support which any section of a slab derives from the contiguous portions; and this is a consideration that must influence us in fixing values of f for adoption in practice. Looking generally at the records of the experiments mentioned, and proceeding upon the assumption that our concrete is to consist of about 3 or 4 parts of coarse aggregate and 2 parts of sand to 1 of cement, we suggest the following values for f:

With concrete	1	week	old	f =	30
" "	4	"	"	f =	58
" "	8	"	"	f =	100
" "	12	"	"	f =	140
" "	6	months	"	f =	200
" "	1	year	"	f =	300

These are rough approximate values, and it is pretty evident that any attempt at closer accuracy would be useless. The following table shows the strength of concrete floors for various spans, calculated according to the above figures:

CALCULATED STRENGTH OF FLAT CONCRETE FLOORS.

Thickness in inches.	Span, in inches.	Breaking weight distributed in pounds per square foot for concrete of the undermentioned ages.					
		1 week.	4 weeks.	8 weeks.	12 weeks.	26 weeks.	52 weeks.
4	24	160	309	532	744	1,065	1,597
5	30	160	309	532	744	1,065	1,597
6	30	228	444	766	1,071	1,533	2,300
6	36	160	309	532	764	1,065	1,597
7	36	216	420	724	1,014	1,449	2,173
8	36	282	549	946	1,323	1,893	2,840
8	40	228	444	766	1,071	1,533	2,300
8	48	160	309	532	744	1,065	1,597
9	48	201	390	675	945	1,350	2,025
9	54	156	303	526	735	1,053	1,580
9	60	130	249	432	603	864	1,296

The safe load should under no circumstances exceed one-third of the breaking weight, and one-quarter or one-fifth is preferable for moving loads.

LONDON MASTER PLUMBERS' BANQUET.

The Master Plumbers' Association of London, Ont., celebrated its inauguration on the 19th of May by a banquet at the Grigg House, at which about fifty persons were present. There were noticed, among others, Mr. Stephens, J. Haslett, jun., Mr. Allen, James Haslett, sen., W. Skelly, jun., Wm. Joanes, John Law, C. W. Walker, Robert H. Geldart, Armon W. Irwin, G. Craddock, Herbert Mathews, Wm. Smith, Wm. Skelly, sen., Frank Bickley, Chas. Williamson, Thos. L. Partridge, E. Holland, A. Millan, C. Needham and Mr. Coleman, all of London. The guests from outside places were President W. J. Burroughes, vice-president Alex Fiddes, and Messrs. Andrew Mann and William Mansell, of the Toronto Master Plumbers' Association, and Mr. Flaherty, of St. Thomas. The city was represented by Ald. Skinner, Dr. Hutchison, Medical Health Officer, and Ald. Armstrong.

An efficient chairman was found in the person of the president, Mr. R. J. Haslett.

After the menu had received proper attention, the President made his opening remarks and proposed the toast of "The Queen," which was followed by that of "The Governor-General" and "Canada, Our Home," all of which were fittingly responded to.

The toast of "The Mayor and Corporation of London" was replied to by Ald. Skinner and Armstrong, who urged the necessity of sanitary improvement.

The other toasts were: "Master Plumbers' Association," responded to by Messrs. Burroughes, Mansell, Smith and Fiddes; "Board of Health," acknowledged by Dr. Hutchison and Ald. Skinner; "The Manufacturers and Wholesale Supply Men," which brought responses from Messrs. Mann, Allen, Stephens and Coleman; and "Our Guests," to which was coupled the names of Messrs. Matthews and Craddock.

The members of the Association were well pleased with the success of their initiatory dinner, which it is hoped will become an annual affair. The local officers are:—President, R. J. Haslett; Vice-President, W. Smith; Second Vice-President, W. Skelly; Treasurer, T. Partridge; Secretary, W. Skelly, jr.; Master at-Arms, C. W. Walker. Members: J. R. Haslett, C. Needham, A. Milne, W. H. Heard, F. Bickley and E. Holland.

The Association is making arrangements for the appointment of an inspector of plumbing.

The cubical outline gives the most volume and floor space for a given amount of material and expense. A floor 30x30 gives 900 square feet of area to 120 feet of wall; the same amount of wall arranged in an ell of 30x30x15 give only three-fourths as much area, or 675 square feet. The cubical form can be worked up artistically by giving grouped windows, and by making the eaves, chimneys and roof bold and striking.

Brick walls should be well bonded. The "English bond," in which courses of headers alternate with courses of stretchers, is probably the strongest. Tarred bricks soon blister and wash, and mortar does not take hold of them. Rough bricks, if laid with red or black mortar joists, are very picturesque. Stone trimmings for red brick walls should be of some warm color, as brown, red, buff or green. Terra cotta makes admirable trimmings for brick walls. The foundation stones should lie on their "natural beds," and they will be stronger therefor.

REVISED ENGLISH WORKING RULES.

The following revised working rules for bricklayers, approved by the Association of Master Builders and the Operative Bricklayers' Society of London, Eng., will doubtless be of interest to Canadian master builders :

There are to be fifty working hours during forty weeks, forty-seven hours during six weeks and forty-four hours during six weeks. Overtime when worked at the request of employers, but not otherwise, shall be paid at the following rates, namely, from leaving-off time until 8 p. m., time and a quarter ; from 8 p. m. to 10 p.m., time and a half ; after 10 p. m., double time. No overtime shall be reckoned until each full day has been made, except where time is lost by stress of weather. On Saturday the pay for overtime, from noon to 4 p. m., shall be time and a half, and after 4 p. m., and Sunday, double time. Christmas Day shall be paid for the same as Sunday. Workmen engaged on a night gang shall be paid one penny per hour in addition to the ordinary rate of wages. One hour's notice to be given or one hour's time be paid by either side, on determining an engagement. All wages due to be paid at the expiration of such notice, or walking time if sent to yard. In the event of more than 10 per cent. of the workmen of the trade employed at the job giving notice to leave during any one day (except Saturday), they are not to be entitled to receive their money until noon on the following day. Men who are sent from the shop or job, including those engaged in London and sent to the country, are to be allowed as expenses 6d. per day for any distance over six miles from the shop or job, exclusive of travelling expenses, time occupied in travelling and lodging money. Payment of wages is to commence at noon or as soon thereafter as practicable on Saturday, and be paid on the job. But if otherwise arranged, walking time at the rate of three miles per hour to be allowed to get to the pay-table at twelve noon. Employers are to provide where practicable and reasonable a suitable place for the workmen to have their meals on the works, with a laborer to assist in preparing them. Wages earned after leaving-off time on Friday and Saturday only shall be kept in hand as back time. If application be made to any employer by the central committee of the Operative Bricklayers' Society to discharge any workman on the ground that such workman is obnoxious, and the employer refuses to accede, no strike shall be sanctioned, but the question shall be referred to the decision of the Board of Conciliation. But no such application shall be made in consequence of such workman belong or not belonging to any trade society. Six months' notice on either side shall terminate the foregoing rules.

Small Leaks.

Much of the loss suffered on contracts is due frequently to the carelessness of the foreman of works or to the men employed in not taking proper care of the materials left in their charge previous to their being put in place. In the loading and unloading of bricks many dollars may be lost or saved by handling. A careful handler will gather up the bricks with due attention and place them in piles without making unsaleable "bats" of an undue percentage of them, whereas a careless man will destroy in a day, while handling and piling bricks, more than would pay his day's wages, and this loss, on a building containing two or three hundred thousands of bricks, would make serious inroads in the profit percentage. When bricks are to be stacked up before being laid in the wall, a good solid and level foundation should be prepared, and laid over with rough plank or boards, and the bricks should then be placed on the boards in regular courses "headers and stretchers," breaking joints as though placed in the wall. By this means the pile or stack will be made solid and insured against falling. It is a good plan to scatter a thin layer of straw on every fourth or fifth course ; it has a tendency to keep the courses even and prevent them crushing the lower courses, and the straw also acts as a bond and ties the stack together.

Care of Lumber.

Perhaps the biggest "leak" in a contract will be found in the lumber bill. From experience we know that a much larger percentage of loss usually occurs in the construction of a building than is generally provided for, and this loss is not due to actual and necessary waste, but rather to bad calculation and careless handling. Finished stuff, such as flooring, wainscotting, base mouldings and door and window trimmings, are carted to the building, thrown down carelessly into a hall room, or perhaps left outside, and for hours, and sometimes days or weeks, is tramped over by the workmen before being used, or as is often the case, left outside of the building, or some place where it is exposed to the weather and rendered unfit to work. The trampling over splits, breaks, fills with sand or disfigures a lot of good material, either rendering it unfit for use or making it necessary to expend a lot of work upon it to make it serve its purpose, all of which could be avoided if proper care was taken in "housing" the material the moment it arrives at the works. Trimmings, doors, mouldings, wainscottings and ornamental wood-work of any sort, ought never to go into a building until all the walls have been plastered complete, and thoroughly dry. The practice of trimming doors and windows immediately after the "putty coat" is applied to the walls cannot be too much deprecated. The custom is an evil one and often causes a great deal of trouble in both doors and windows, as the "trim" by expansion is apt to crowd the jambs, causing the sashes to bind and stick, and forcing the door jambs out of shape, causing trouble with the locks and often leaving a defect that can never be remedied. Where time is an important factor, it may be permissible to "put" down base, or even to plant "matched" wainscot, but neither time nor conditions should force the contractor to put on his trimming while the plaster is yet damp, if he values his reputation as a good and careful workman.

Concerning Floors.

In the matter of floors contractors may add to their profits or increase their losses more rapidly than in any other class of work about a building. A careful workman will see that his joists are properly sized before being placed on the wall, and that the "crowning edge" is above, and he will endeavour when "bridging" to give all his joists a crowning edge and have them all on one plane so that his flooring will touch each joist without being forced down or sprung. This is an important matter, inasmuch as if the joists are at irregular heights, it will cause a great deal of trouble in laying the floor and result in a big loss of time, which is loss of money. In driving flooring together some care should be taken, and the tongues of the boards should not unnecessarily be broken off or "mashed" in driving the stuff together. If any difficulty arises in getting down the floor on account of the machine work, the flooring should be discarded at once, as it is the height of folly to wrestle with a lot of badly matched flooring. It will pay two or three times over to have the stuff run through the machine again than to fool away time in trying to make a good job with impossible materials. Well matched flooring should "lay down" with ease and the edge joints should be invisible. In tongue or blind nailing there is no necessity for breaking the tongue where each nail is driven, neither is there any necessity for the mark of the hammer to be seen wherever there is a nail. A man who will persistently leave "his X mark," engraved with a claw-hammer, on every joint of flooring, should be taken from the work at once and given something to do more suitable to his capacity. By a proper cutting of lengths, from 5 to 15 per cent. of the material may be saved, and the shrewd workman, who has the interest of his employer at heart, will always manage the disposition of his "butt joints" so as to have a minimum of waste. When a man fills a room with sheet ends of flooring while laying, he may be put down as an extravagant floor layer. It may be he can lay more surface in a day than another man who does not have so many butt ends, but as a matter of fact, the man who puts down the lesser surface of floor and makes less waste, is often the more profitable man for the contractor. The slasher and rusher who gets in a lot of work each day at an extra waste of material, is profitable only to those who use kindling wood.

Lime and Mortar.

In country places where lime has to be hauled a long distance, proper provision should be made for its preservation when it arrives at the works. In a damp atmosphere a cartage of ten or twelve miles may cause a load of lime to be partly slaked before it reaches its destination, and in cases of that kind, it would be better when possible, to run it in the bed at once and finish the slaking ; then nearly the full virtue of the lime may be captured. When this can not be done the lime should be put in a dry place and used as soon as possible. Lime should never be stored in a cellar or in any place where it is damp, as it will lose half its virtue in a very short time in such a place, and the mortar made with it will never give satisfaction. Good live sand is a necessary requisite for making good mortar, and the contractor should see to it that such is furnished to the plasterer. Dead sand, while easy to work, never makes a good job, and mortar made with it soon rots and crumbles away from the wall. It is the silica in the sand that combines with the lime, that forms the hard solid mortar we find on some of our old houses. Good long hair that has been washed, should be used in the mortar in proper proportions to insure good work. Plasterers, as a rule, stint the hair in their mortar as a matter of economy, but this is wrong, and in a measure dishonest. To insure good and lasting work, the mortar should not be used until it has been made at least ten days. It will be better to stand fourteen days if conditions will permit. The best results in plaster work are obtained with well made mortar that has been made one month or more before being used.

Much carelessness, and consequently much loss, are connected with the piling up of rough lumber preparatory to being used in a building. We have frequently seen joists, studding, rafters, roof-boarding and rough sheeting, thrown off a wagon or sleigh pell-mell without any attempt made to prevent the breaking, splitting or warping, and left in an open pile, exposed to the weather, and perhaps in such a position that it would be trampled over by the workmen or others. The breaking of a joist, a stud or a rafter, or the splitting of a board, or the warping or twisting of any of them out of shape, is loss that will be felt at the wind-up of the work, and the multiplication of these breaks, splits and twists, often make invisible gaps in the profits, and the shrewd contractor will insist on having all his stuff properly and carefully piled in the grounds, and covered with rough boards to keep out the weather, or will otherwise protect his materials. More money is made by giving prompt attention to little matters of this sort, than in "rushing" the work in undue haste. A careful workman must have time to make good work, and a careful workman will, as a rule, save to his employer in material whatever it costs in extra time to do the work ; besides producing work that brings honor to employer and workman.

No good house, frame, brick or stone, should be without one or two fire-places in it, and in the country villages and towns, where the contractor has much to do with designing the house, he should make it a point to impress on the owner the importance of having open fire-places of some sort in the house. When only one of these can be in the house, it should be in the dining-room, as that is the room where the family will be the most of the time they are in the house together. If two or more fire-places can be placed in the house, then one should be in the dining-room, one in the parlor, and a third in the bed-room that is oftenest occupied. If the fire-place is intended for wood altogether, it may be built without a grate, as fire-dogs or andirons may be used on a thick cement or brick hearth. It would be better, however, to build in grates in all the fire-places, as then the opening would be less, and the chimney draught could be better regulated. A good English grate, with tile facings, can be purchased for $15 or $16, and it can be made to do good service with wood as well as with coal. Of course, in our Canadian climate, open fire-places can not be depended on for heating during midwinter, but in spring and fall, when stoves are taken down, or heating by steam, hot-water or hot-air, is discontinued, they do the work effectually. They also act as health preservers, as no device yet put in practice in domestic architecture, can equal the open grate as a mode of ventilation. Where cost is not a great obsticle, it would be better to have an open fire-place in the dining-room without grate, having a "basket" in place. These baskets cost about as much as an English grate—perhaps a little more if damper, etc., are included. And the fire-place will require a little more work to make it suited to the basket. The whole chimney heart may be of exposed brick work. The upper portion above the shelf may drop back four inches, and a neat plain cornice may project from the heart under the shelf, forming a finish, with the shelf (which should be of hardwood) of a mantel. The skilful bricklayer should be able to make a handsome brick mantel if he picks his stock, rubs their faces, lays in fine mortar, and lines up his joints. In a mantel of this kind there is a big opportunity for the bricklayer to display his skill. This makes a mantel without wood, save and excepting the shelf, which may or may not have a moulded edge to suit the brickwork.

TRUTH IN ARCHITECTURE.

By W. E. Doran, Architect, Montreal.
(Concluded from May Number.)

There is no such thing as human perfection, yet the law says his work must be perfect—not only his own work, but he is obliged to see that the work of every cheap Jack whom the cupidity of his client obliges him to employ shall be perfect; he must be omniscient; he must know beforehand the nature of every soil, its powers of sustaining weight, the nature of every kind of material used in construction, its power of resistance to strains of every description, to time and to weather, the nature and strength of all cements and mortars, the value of all paints and pigments, he must be proficient in sanitary science, in all manners and fads of heating and ventilation, in all the details of electrical appliances. In a word, he must be master of all the arts and sciences to a certain extent, and then his powers of observation must be limitless; he must foresee against all possible flaws in materials, all willful or unintentional delinquencies on the part of builders; as a consequence he is not profound, his knowledge is encyclopedic and smattering—he can belong to no particular school; in fact we can hardly recognize any such thing as a school in architecture to-day.

Again national characteristics have almost ceased to exist. In the olden times, when travel was rare, national characteristics were developed by isolation from the rest of the world; a pupil followed exactly in his master's footsteps and improved thereon as far as in him lay. If he did travel, what he sought was to improve his own knowledge, and to graft on his own style anything his taste would find congenial to it, not for the introduction of absolutely new and startling effects. He worked in supreme disdain of the multitude; to-day he must please the popular fancy, he must show himself original, even if he must copy from semi-barbarians to appear so.

The multiplication of the process of illustrations also makes us familiar with the work of the world, hence the almost unconscious plagiarism exhibited by the architects of the world, mutually borrowing from each other until we hardly know which is original—at least it looks as if there was a common stock of ideas and designs the only really original productions of this age being crystal palaces and the tall office buildings, and perhaps I should add the great hotels and the plutocrats' dwellings. When I speak of crystal palaces I include as such the large retail stores the skeletons which frame the plate glass that displays the wealth of merchandise. These necessitated metal construction, and the progress seemed fair enough till greed and the desire to make the most use of land regardless of the right of neighbors to light and air called into existence the monstrosities of seventeen and twenty stories, now promising to reach out to thirty. Dryden, writing of the column of London, said, "like a tall bully it lifts its head and lies." Now this was a libel on the column; it was the inscription which was at fault; but it can be truly said of the modern building that it is in itself a series of lies—the very perspective which the architect makes is taken from a point about half way up. They surely do not imagine the spectator is going on the roof of a moderate sized building or to hang on to one of the cornices of a sister monstrosity in order to view the building. Lie No. 1. Again, the eyes sees piers of brickwork extending skywards ostensibly to support the building which we instinctively know could not support its own weight; we are told the skeleton construction inside of this is all right, the steel work supports the pier, the pier protects the steel and the whole is fireproof. Lie No. 2. Lie No. 3. The whole frame work depends, for retaining its perpendicular upon being tied together in all its parts. The destruction of a few rivets may mean the toppling over of the whole mass. It is a construction requiring, as in bridges, care and supervision, and sometimes renewal of parts, which, enclosed with brick and cement, it can not have. Liable to corrosion, the damp of water services and waste pipes everywhere will hasten the inevitable work of time; the multitude of wires for electrical purposes adds the danger of electrolysis. Granting such a building may survive its designer, has any man a right to commit murder on the unborn? Have we a right to build to-day that which in after years will probably collapse without warning.

It is true that when we build we are not bound to insure permanency, but we are bound in the name of humanity and morality to build in such a way that our structures shall give timely warning of their decay. Truth requires it. I do not wish to be understood as decrying the use of iron and steel in buildings, but what I do advocate is that this construction be tested by the principles of truth, and that the material be protected by coating with copper or other metals which if it cannot prevent decay, will at least retard it, and further will leave any defects that may come, and, which inevitably do appear in all human work, visible to those who might suffer therefrom. There is no such thing as simplicity. This use of exposed iron or steel would therefore lead to an architecture special to itself, and proportions suitable to such construction.

The other two forms of construction, the grand hotel, and the private mansion of the wealthy man, naturally seek the renaissance in their outward form of expression. The renaissance affords the best opportunity of doing this; it lends itself readily, and is universally, and I think rightly, so employed.

Will architecture emancipate itself from these conditions and how? It will take its proper place in modern history when architects adopt modern methods, and the most prominent of these is specialism. In any part specialism is founded upon the principles of its professors being themselves truthful, that is being prepared to admit that while having some knowledge of all the branches of their art or profession, they excel in one or possibly more than one, at all events in a limited number only, and that while claiming pre-eminence in these only, they will call in the aid and assistance of others in relation to branches for which they have neither the inclination nor the time to devote themselves so fully—and these others in their turn would in a similar way consult the former on their specialties and profit by their advice and assistance. Unless a movement of this kind become general it is almost impossible to have it, as naturally A will not consult B on one point if B be not prepared to consult A on another, as this would be an admission of inferiority on A's part; neither will A and B be prepared to openly consult each other whilst C D E and all others pretend to universal knowledge, and the public, their clients, believe them. The first step must be the formation of partnerships, each member of the firm having his particular forte and confining his attention to it.

This will educate the public to the necessity for specialism in architecture as well as in medicine. In the meantime what can individual architects do towards improving the condition of things, and what course can we recommend to our students? Shall we recommend them to neglect all branches except the one they feel they excel in. By no means, but what I should recommend is that while following the general practice of the all round man in its most useful and ordinary branches, they should develop some point in which they know they can and will excel, for the day of the specialist is coming, and soon the all round man will be regarded as a quack. In the meantime every architect, and everyone aspiring to be such, should follow Carlyle's advice, "Avoid shams," and if there is anything in him, produce it.

Of course in cases where circumstances require a certain style to be followed the architect must try and work out his plans so that they will lend themselves as much as possible to it, but when the architect is at liberty in the choice of style it seems to me that the plan should be first developed and studied to a certain extent, and its peculiarities should in a minor degree govern the choice of style, the major consideration being always suitability to the purposes for which the building is intended. If the building be of such a character that no particular style be indicated or required, I think it much preferable to proceed on one's own judgment, and not attempt any labored work when only simplicity is demanded. But if a certain style be chosen, I think the architect should adhere strictly to it as nearly as possible provided he has chosen to follow the period in which that style has reached its zenith.

If, on the contrary, he has chosen an early transitional period, or one in which the style has shown deterioration, he certainly has the same liberty as had the workers of the period which he has chosen to follow in making changes, but these should always tend to bring his work nearer to the best ideal rather than to still further draw it away. While circumstances may sometimes require the use of transitional or debased styles, I think nothing can justify an architect in adopting for the sake of picturesqueness anything that was originally done merely in imitation of better work by men who were ignorant or untrained. On the other hand for the sake of constructive truth, no one should for the sake of strict adherence to style resort to deception.

There is such a thing as conventional truth, and this should never be violated. It makes one shudder to see in an otherwise pleasing building, a long lintel seemingly composed of a number of stones not only hanging in the air, but supporting sometimes an important pier of the superstructure.

Again we see a rounded corner of a building with a lintel which we know could not carry of itself, or a stone bay window corbelled out in seeming violation of all principles of the centre of gravity. How much better would it not be in the first place to show the steel beam with an appropriate treatment and painted to match the stone with a slight difference of shade just to show that it is not pretended to be stone; and secondly, what an improvement an oblique arch would be whilst in the last no amount of tieing in with steel work to the interior construction can justify the unnatural projection in the front.

Speaking of truth naturally raises the question, should materials ever be counterfeited, i.e., should an inferior material be made to look like a superior one? I would say, yes, but it must be conventionally true, that is the richer material if preferable must be such as would naturally be in that place; for instance, I see no objection to marbling a column, providing you do not make a monolith such as is not to be found in the world, or if found, could not be quarried, and provided again that a marble column itself would be suitable in the position of the imitation one. We must remember that art is the imitation of nature, and all that is required of it is that it be conventionally true, but a flimsy material should never be placed instead of a solid one where the solid one only would suit; how ridiculous a tin battlement looks on a house. In the first place a street front in the castellated style is out of place; although the law says every man's house is his castle, they are not made to stand a siege of snowballs, about the only use the mock battlements could be put to.

I have touched on some of these details not in a spirit of criticism, but merely to illustrate the fact that in small things as well as great, there is merit in consistency. We cannot always work in great things or in the channels to which our ambition would lead us, but we can take care that what we do shall be conscientiously and carefully done.

MODERN ORNAMENT.

From time to time attempts have been made to develop and foster new schools of ornamentation, and to throw off the tendency to copy older forms and to substitute new and presumably original designs. Although written more than thirty years ago, the following portion of the concluding chapter of Owen Jones' Grammar of Ornament contains much sound thought upon this subject, especially in view of the extending application of Art to household work.

"Although ornament is most properly only an accessory to architecture, and should never be allowed to usurp the place of structural features, or to overload or disguise them, it is in all cases the very soul of architectural monument.

By the ornament of a building, we can judge more truly of the creative power which has been brought to bear upon the work. The general proportions of the building may be good, the mouldings may be more or less accurately copied from the most approved models, but the very instant that ornament is attempted, we see how far the architect is at the same time an artist. It is the best measure of care and refinement bestowed upon the work. To put ornament in the right place is not easy; to render the ornament at the same time a superadded beauty and an expression of the intention of the whole work, is still more difficult.

Unfortunately it has been too much the practice in our time to abandon to hands most unfitted for the task the adornment of the structural features of buildings, and more especially their interior decorations.

The fatal facility of manufacturing ornament which the revived use of acanthus leaf has given, has tended very much to this result, and deadened the creative instinct in artist minds. What could so readily be done by another they have left that other to do; and have so far abdicated their high position, the head and chief.

How, then, is this universal desire for progress to be satisfied—how is any new style of ornament to be invented or developed? Some will say, a new style of architecture must be found, and we should be beginning at the wrong end to commence with ornament.

We do not think so. We have already shown that the desire for works of ornament is coexistent with the earliest attempts of civilization of every people; and that architecture adopts ornament, does not create it.

The chief features of a building which form a style, are first, the means of support; secondly, the means of spanning space between support, and thirdly, the formation of the roof. It is the decoration of these structural features which gives the characteristics of style, and they all follow so naturally one from the other, that the invention of one will command the rest.

It would appear at first sight that the means of varying these structural features had been exhausted, and that we have nothing left but to use one or the other of the systems which have already run their course. Let us not despair; the world has not seen, most assuredly, the last of the architectural systems. If we are now passing through an age of copying, and architecture with us exhibits a want of vitality, the world has passed through similar periods before. From the present chaos there will arise, undoubtedly, (it may not be in our time) an architecture which will be worthy of the high advance which man has made in every other direction towards the possession of the tree of knowledge.

To return to the subject, how is any new style of art or of ornament to be formed, or even attempted to be formed? In the first place, we have little hope that we are destined to see more than the commencement of the change; the architectural profession is at present too much under the influence of past education on the one hand, and too much influenced by an ill-formed public opinion on the other; but the rising generation in both classes are born under happier auspices, and it is to them we look for hope in the future. It is for their use that we have gathered together these works of the past; not that they should be slavishly copied, but that artists should, by an attentive examination of the principles which pervade all the works of the past, and which have excited universal admiration, be led to the creation of new forms equally beautiful.

We believe that if a student in the arts, earnest in his search after knowledge, will only lay aside all temptation to indolence, will examine for himself the works of the past, compare them with the works of nature, bend his mind to a thorough appreciation of the principles which reign in each, he cannot himself fail to be a creator, and to individualize new forms, instead of reproducing the forms of the past. We think it impossible that a student fully impressed with the law of the universal fitness of things in nature, with the wonderful variety of form, yet all arranged around some few fixed laws, the proportionate distribution of areas, the tangential curvature of lines, and the radiation of a parent stem, whatever type he may borrow from nature, if he will dismiss from his mind the desire to imitate it, but will only seek to follow still the path which it so plainly shows him, we doubt not that new forms of beauty will more readily arise under his hand, than can ever follow from a continuation in the prevailing fashion of resting only on the works of the past for present inspiration. It will require but a few minds to give the first impulse: the way once pointed out, others will follow, readily improving, till another culminating point of Art shall be again reached to subside into decline and disorder. For the present, however, we are far enough removed from either stage."

MANUFACTURES AND MATERIALS

GRANITE FOR THE UNITED STATES.

The granite quaries of Messrs Tayte, Meating & Co., at St. george, N. B., from which the red granite is being obtained for the American Museum of Natural History on Manhattan Square, New York, presents an active scene. There have already been shipped 3,500 feet, while other vessels will shortly go forward with further consignments.

Between 55 and 60 men are employed in the quarry getting out the stone and conveying it to the station for shipment. The firm are said to be doing the work which they have in hand in an eminently satisfactory manner. Extra machinery will be put in at once and the output considerably increased. The architect at New York and the port comimssioners have approved of the granite, and it is probable further orders will be placed with the company for the American market.

SLATES AND SLATING.

The best and most substantial roof known to the architects at present is the slate roof, having at least a square pitch. Such a roof weighs considerably more than a shingle roof, and it also costs a little more, but it is many times more durable.

Some technical terms are used in connection with slating. In England names are used to indicate the size of slate. One 10 × 13 inches being known as a double. Smaller slates are called small doubles. The next larger size is known as plantations; the next size is called viscountess. Sizes ranging from 8 × 12 inches to 10 × 16 inches are called ladies; from 10 × 20 inches are called countesses; up to 14 × 24 inches, which are known as princesses. There are slates that run through all the title of nobility, marchioness, duchess, imperial, and then comes what is probably a poor man's slate, under the delicate title of rags. The noble titles are again resumed, and run queens, empresses, and end with princesses.

In American practice the slates run simply by inches, from 7 × 14 up to 17 × 24 inches. The thickness of slates ranges from 0.125 to 0.3215 of an inch, and their weight varies from two to four and a half pounds per square foot. A square of slating is rated as any other roofing equal to 100 square feet, the gauge is the distance between the courses, while lap is counted as the distance which each slate overlaps the slate lengthwise next below but one. Lap varies from two inches to four inches, and a standard lap about three inches. As above stated, a good slate roof should have about square pitch, but slates should never be put upon a roof which pitches less than one foot in four feet. When it is desired to compute the surface of a slate when laid and the number of squares of slating, subtract the lap from the length of a slate, which is taken as distance from nail hole to tail, and one half the remainder will give length of surface exposed; this, when multiplied by width of slate, will give the surface required.

To ascertain the number of slates required for a square, divide 14,400, which is the area of one square in inches, by the surface obtained above, and the quotient will give the number of slates required for one square. For an example, take a slate 12 × 24 inches; taking a standard lap three inches, the number required for a square will be found by subtracting three from twenty-four, equal to twenty-one, and twenty-one divided by two equals ten and a half inches, which, multiplied by twelve, equals 126 inches, 14,400, the total area to be covered, divided by 126, which equals the area of one slate, gives 114.29 slates required for the square.

Slate weighs from 165 pounds to 180 pounds per cubic foot, and in consequence of lap, it requires an average of two and a half square feet of slate to make one inch of slating. When slate 0.125 inch thick is laid on laths, it weighs 4.75 pounds per cubic foot; when the same is laid on one inch boards it weighs 7.75 pounds per cubic foot. Slate 0.1,875 inch thick on laths and boards weighs seven and nine pounds respectively. A 0.25 inch slate weighs 9.15 and 11.25 pounds respectively. The thickest kind, gauging 0.3,210 inch, weighs 11.15 pounds and 14.10 pounds on laths and boards.

A slate roof composed of 6 × 13 inch slate weighs 1,680 pounds per square, and requires 480 slates. A 10 × 20 inch weighs 6,720 pounds, and requires 171 slates per square. A 12 × 24 inch slating requires 125 slates, and weighs 4,480 pounds. Stone.

ROOFING TILES OF WOOD PULP.

One of the latest things in the way of roofing tile is made of wood pulp, the goods being turned out by an enterprising Norwegian firm doing business in Christiania. The roofing material is known as Norway tiles, the pulp under high pressure being formed into thin cakes of sizes similar to ordinary roofing slate. After a chemical treatment, which is the inventor's secret, the tiles become hard like brick, and attain a deep black appearance, which lends itself admirably to give a soft tone to houses with prominent roofs and gables. It is claimed for the Norway tiles that they possess every advantage of the best slate in the market; their composition makes them light and durable, and they are not so liable to breakage as ordinary slate. They are not subject to any expansion or contraction, and when a roof is once covered with this material, it will stand for a good many years without any repairs whatever. Prominent architects in Norway who have had the opportunity to examine the tiles pronounce them superior as to quality, appearance and price, and the insurance companies seem to regard them as a very desirable and safe roofing material.

The town of St. Johns, Que., has granted a bonus of $20,000 to "La Societe Anonyme des Fainciers du Canada," of France. This is the company which has been negotiating for the St. Johns Stone Chinaware Company's potteries, the granting of the bonus practically closing the deal. The terms of the bonus are $2,000 per annum for ten years, conditionally upon the company employing not less than 150 hands for 11 months in the year, with a pay roll of not less than $40,000 a year. It is understood that possession of the property in St. Johns will be taken almost immediately, and that these potteries will shortly be operated on a large scale. The new concern is made up of wealthy and practical men, and their intention is to manufacture, not only ordinary crockery, but a fine class of porcelain ware on a large scale.

The striking carpenters in Buffalo have given information that contractors were importing alien labor from Canada, and the authorities are taking steps to prosecute the offenders.

THE LATE MR. J. B. RESTHER.

The late Jean Baptiste Resther, architect, of Montreal, Que., whose death on the 14th ult., at the age of 66 years, was briefly noted in our May issue, was born in Montreal, July 17th, 1830. He was the son of the late John Ignace Resther, a contractor of that city, and brother of the Rev. Father Resther, of the Jesuit Order. He received his education in the Christian Brothers school and under private tutors. Mr. Resther, after spending a short time as dry goods clerk, commenced with his father as Clerk of Works for the construction of the Bonsecours Market in 1847. In 1849 he left Montreal for St. Hyacinthe, where he was contractor for the college. He subsequently took a contract for the building of all the stations for the G. T. R., from St. Thomas

The Late Mr. J. B. Resther.

down to Riviere du Loup. While in St. Hyacinthe he was for several years a member of the Council. In 1867 he returned to Montreal, and opened an office as architect, arbitrator and valuator, in which profession he had a large practice. He erected a large number of private and public buildings in and around Montreal, the Exhibition Buildings among others. In 1884 Mr. Resther was chosen first vice-president of the St. Jean Baptiste Association, in which he had always taken a deep interest. He was a leading member of the Architects' Association of the Province of Quebec. He was connected with many important cases of arbitration for the government, railway corporations, etc., in which he distinguished himself.

CHIPS.

A consignment of slates of excellent quality has recently been received in England from Canada.

The organization of a master plumbers' association in Hamilton has been effected. The officers are: Wm. Fairley, president; W. J. Walsh, vice-president; Hugh Wallace, secretary; Adam Clarke, treasurer; Wm. Smith, sentinel.

The president of the Carpenters' and Joiners' Union of British North America recently interviewed the Controller of Customs urging the necessity of reducing the duty upon certain tools used by carpenters and joiners. Some special classes of tools cannot be obtained in Canada, and on these purchasers are obliged to pay a large duty.

At a recent meeting of the local Board of Health at Toronto, the Medical Health Officer informed the board that he intended exercising a personal supervision of the inspection of plumbing, and with that end in view he had given instructions that all applications for inspection must be made at the office, and would be attended to in order of priority. He promised that there should not be any delay in the work, and requested that, if there is any, the matter be reported to him at once.

The old lodge at the west corner of Queen street and University avenue, Toronto, the only survival of four similar structures placed at different entrances to the University and Queen's Park, has been demolished within the past fortnight. It was built by Mr. J. G. Howard, architect and civil engineer, in the year 1832. Its companion, formerly situated on the opposite corner, was torn down some 12 years ago. These two lodges were occupied respectively by Mark Fitzpatrick and George Stacey, who acted as caretakers and gatekeepers at the two entrances.

PERSONAL.

Mr. F. H. Herbert, architect, Toronto, has removed to new offices in York Chambers, 9 Toronto street.

Mr. W. H. Carrick, vice-president of the Gurney Foundry Co., of Toronto, sailed on the steamer Umbria for Great Britain.

Mr. R. C. J. Dunn, architect, St. John, N. B., has removed to new quarters in the Vaughan building on Prince William street.

Mr. Joseph Simmons, builder, of London, Ont., is incapacitated from his duties by a sprained wrist, the result of a fall from his waggon.

Mr. Eugene C. Larose, architect, formerly in the employ of Mr. James R. Brown, architect, of Montreal, has taken up his residence in Ottawa.

Miss Laura Cooper, daughter of Mr. Jos. Cooper, contractor, of Ottawa, was recently married to Mr. Wm. Dewar, of the Canada Atlantic Railway.

Mr. Louis Champeau, a well-known contractor of Montreal, died at Cote des Neiges on the 4th inst., at the age of 72 years. He was taking a rest at his summer cottage.

The wedding is announced of Miss Bertha Wright, of Ottawa, and Mr. Robert Carl Harris, C. E., professor of civil engineering and architecture at the Royal Military College, Kingston.

Mr. C. M. Robertson, secretary-treasurer of the James Robertson Co., Ltd., Toronto, is receiving the congratulations of his friends upon his recent marriage. The bride is Miss West, of the same city.

Messrs. W. J. Burroughes, A. Fiddes and Joseph Wright will look after the interests of the master plumbers of Toronto and the west at the approaching convention in Montreal to organize a Dominion Association.

Mr. James Sinclair, contractor, of Toronto, with his wife and family, have left for an extended tour in Europe. Mr. Sinclair is a native of Sutherlandshire, Scotland, where his presence will by welcomed by his many friends.

A visitor to Winnipeg recently was Mr. J. E. Murphy, of Owen Sound, Ont., vice-president of the Owen Sound Portland Cement Company. His purpose was to introduce his material amongst architects and builders.

While Mr. John Dryan, contractor, of London, was driving on Clarence street, his rig collided with a trolley car, by which he was thrown out upon the pavement. He was rendered unconscious, although not seriously injured.

Mr. John Allen, the well-known contractor of Montreal, has accepted the invitation to represent St. Antoine ward in the City Council, to succeed Hon. A. W. Atwater, who resigned when he accepted the portfolio of Provincial Treasurer. Mr. Allen is an enterprising business man, and has executed many large contracts.

A well-known builder in the person of Mr. James Edgar, of Toronto, is dead. Mr. Edgar had suffered for some time from inflammatory rheumatism, which resulted in this death at the age of 75 years. Mr. Edgar was foreman under Mr. John Worthington at the building of St. James' Cathedral, University College and the forts at Quebec.

A worthy citizen and prominent contractor of Toronto was removed i the death of Mr. Robert Rennie, which occurred towards the close of the month of May. The deceased was born in Aberdeen, Scotland, on March 7th, 1822. In the year 1854 he came out to Montreal, where he lived for a few months and then removed to Toronto, where he has resided ever since. On settling in Toronto he entered into partnership with Mr. C. Duthie, caarrying on business as roofers. After being in business with Mr. Duthie for a few years they dissolved partnership, and Mr. Rennie commenced business in the same line on his own account. About ten years ago his son, Robert B., was taken into partnership, under the name of Robert Rennie & Son. The firm remained in business until about two years ago, when he retired, leaving the business in the hands of his son, who still continues it under the old firm name. Mr. Rennie was noted for his upright business dealings and punctuality. He was a Presbyterian in religion, and a staunch Reformer in politics.

Frank Dean, jr., of Hamilton, Ont., is applying for patents on a brick kiln to burn all hard brick with soft coal. Formerly they have been burned with wood, and in consequence a great many soft brick have to be used in the construction of buildings, soaking up a great deal of dampness as a result.

An Alexandria exchange says that Mr. Borque, the contractor for the new Dominion Reformatory, has commenced the work of laying the walls. A boom derrick for horse power has been erected, and another one is about completed. It is, we believe, intended to dress the stone at the quarry, so that it will be ready for use when laid down at the site of the building.

DOMINION MASTER PLUMBERS' ASSOCIATION.

On July 2nd next there will be held in the city of Montreal a convention of master plumbers of the Dominion, with the main object of forming a Dominion Association. At present local Associations exist at Montreal, Toronto, Halifax, St. John, London, Quebec and other points, the former being the only one incorporated by the government, and capable of entering and defending legal suits as an Association.

The existing Association in Montreal was formed in August, 1884. Previous to that time there existed an Association which was amalgamated with the Contractors' Association as a branch. In the following year an Association was formed in Toronto. These two branches can justly be said to be the father of the present movement for the formation of an Association representing the Dominion, and it is pleasing to know that the promoters have received every encouragement and hope that their efforts will be crowned with success.

All the preliminaries in connection with the convention have not yet been arranged, but from a number of cities and towns word has been received that delegates will be sent. The local Associations will be maintained as at present, and where possible new ones organized, by whom all local questions will be considered.

The Dominion organization will grapple with such questions as affect the trade generally, and by its means it is hoped to accomplish many needed reforms in the plumbing by-laws of the various cities which will ultimately result beneficially to the public at large.

It is the intention to amalgamate with the Master Plumbers' Association of the United States.

It is claimed that too often the persons who comprise the Board of Health in our cities are men entirely unfitted for the position, with little knowledge of the duties which they are called upon to perform.

Such being the case, the plumber is often called upon to execute work in a manner which he knows to be defective, but which he is, nevertheless, obliged to carry out.

It is hoped the master plumbers will be successful in organizing a strong Association which will be the means of raising the status of the trade and also prove a benefit to the public at large.

A DISSENTIENT VIEW.

To the Editor of the CANADIAN ARCHITECT AND BUILDER.

SIR,—With your permission I would like to express my dissent from the view stated in an editorial paragraph in THE ARCHITECT AND BUILDER for May on the subject of farm house architecture. In the paragraph referred to pleasure is expressed at seeing pressed brick, plate and colored glass employed of late in the construction of this class of buildings. On the contrary, I think it a matter for regret that such materials should be used. The ideal farm house is one constructed with local materials and in a style as far removed as possible from that of the city residence. It should have an air of homely comfort. Nothing is to my mind more out of place than a farm house with the appearance of having been designed for a 25-foot city lot. I have in mind such a house erected by the M. P. for a rural constituency. A little way distant from it stands an old fashioned farm house with low eaves and long facade and verandahs facing the highway. The contrast is strongly in favor of the older house. The practice of importing city houses into the country should be discouraged.

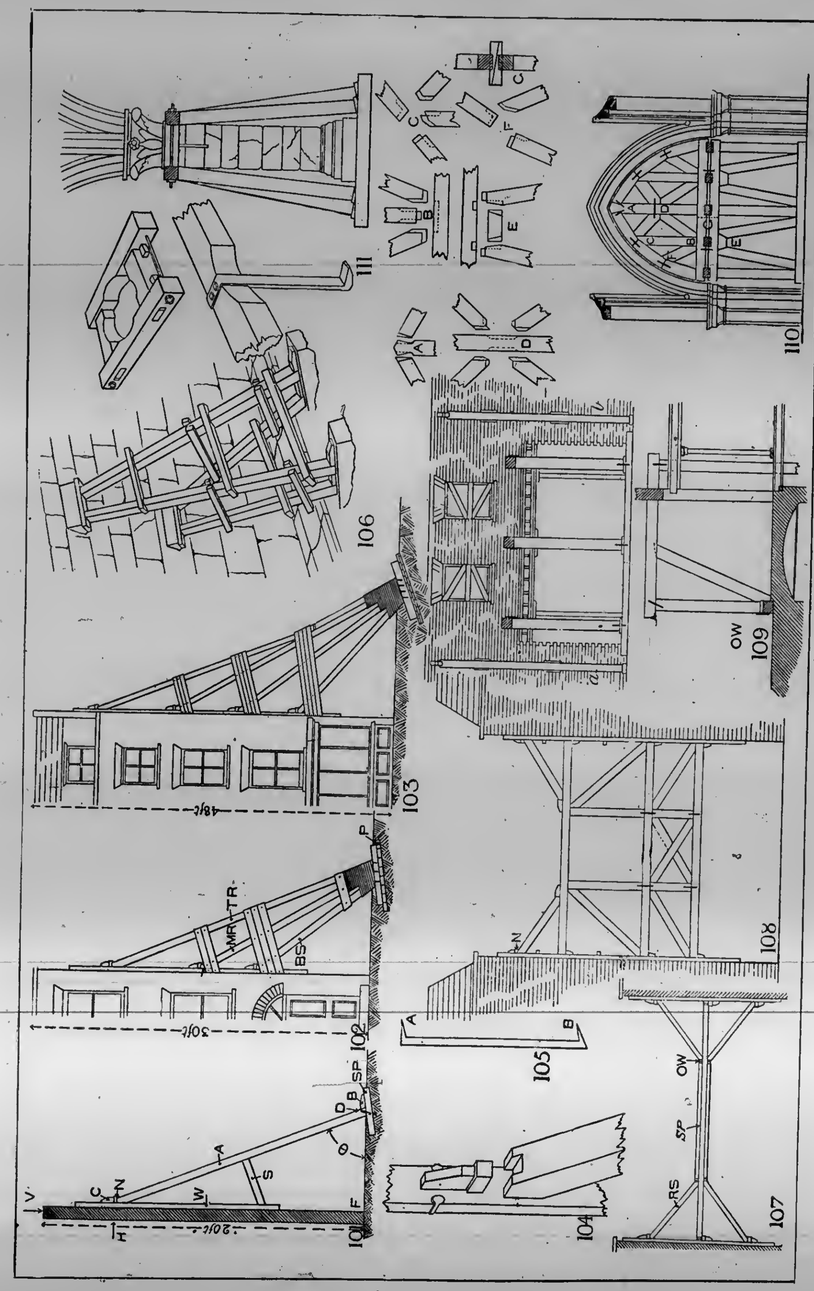
STOKESAY CASTLE—DRAWN BY EDWARD SWALES.

RESIDENCE, SPADINA ROAD, TORONTO.
CURRY, BAKER & CO., ARCHITECTS

PLAN OF STOKESAY CASTLE.
DRAWN BY EDWARD SWALES.



From THE "BUILDER."

SHORING AND STRUTTING.

101, Raking Shore; simplest form. 102, Raking Shore; most frequently used. 103, Raking Shore; adapted for very high buildings. 104, Detail showing notching of head to needle. 105, Correct and Incorrect Form of Dog. 106, Strong Combined Shore. 107, Flying Shore. 108, System of Flying Shores. 109, Needling required to support a wall. 110, Special form of Shoring used at Grosmont Church, Ill.; Shoring used to support Cap of a Cylindrical Column.

CANADIAN ARCHITECT AND BUILDER.

VOL. IX.—NO. 7. JULY, 1896 PRICE 20 CENTS $2.00 PER YEAR.

—THE—

CANADIAN ARCHITECT AND BUILDER,

A Monthly Journal of Modern Constructive Methods.

(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD).

PUBLISHED ON THE THIRD THURSDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

C. H. MORTIMER, Publisher,

Confederation Life Building, - TORONTO, CANADA.

Telephone 2362.

Branch Office: NEW YORK LIFE INSURANCE BUILDING, MONTREAL.

Bell Telephone 2299.

SUBSCRIPTIONS.

The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.

Prices for advertisements sent promptly on application. Orders for advertisements should reach the office of publication not later than the 12th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of technical value to the persons in whose interest this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publisher of any irregularity in delivery of paper.

ONTARIO ASSOCIATION OF ARCHITECTS.

OFFICERS FOR 1896.

PRESIDENT	H. B. GORDON, Toronto.
1ST VICE-PRESIDENT	J. GEMMELL, Toronto.
2ND VICE-PRESIDENT	JOS. W. POWER, Kingston.
TREASURER	EDMUND BURKE, Toronto.

COUNCIL:

F. J. ALEXANDER	Ottawa.
THOS. FULLER	Ottawa.
E. J. LENNOX	Toronto.
J. M. MOORE	London
W. R. STRICKLAND	Toronto

REGISTRAR AND LIBRARIAN:

W. A. LANGTON - Canada Life Building, Toronto.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.

OFFICERS FOR 1896.

PRESIDENT	A. C. HUTCHISON, Montreal.
1ST VICE-PRESIDENT	A. T. TAYLOR, Montreal.
2ND VICE-PRESIDENT	J. P. PEACHY, Quebec.
SECRETARY	J. VENNE, Montreal.
TREASURER	JOSEPH PERRAULT, Montreal.

COUNCIL:

CHAS. BAILLAIRGE	Quebec.
ROHT. FINDLAY	Montreal.
J. Z. RESTHER	Montreal.
A. H. LAPIERRE	Montreal.
G. E. TANGUAY	Quebec.
THEO. DAOUST	Montreal.

AUDITORS—A. J. FOWLER and C. CHAUSEE, Montreal.

TORONTO BUILDERS' EXCHANGE.

BOARD OF DIRECTORS:

JOHN ALDRIDGE, President.
THOS. CANNON, Jr., 1st Vice-Pres.
JOHN VICK, 2nd Vice-President.
DAVID WILLIAMS, Treasurer.
WM. BOOTH.
JOHN WICKETT.
JOHN RUSSELL.
H. LUCAS.
JOHN VOKES.
JAS. CRANG.
JOHN M. GANDER.
GEORGE HENRY.

JOHN L. PHILLIPS, Secretary.

TO ADVERTISERS.

For the benefit of Advertisers, a copy of this Journal is mailed each week to persons mentioned in the CONTRACT RECORD reports as intending to build, with a request to consult our advertisement pages and write advertisers for material, machinery, etc.

Iron Construction for Churches.

IRON, which of late has so largely superseded brick, stone and wood in the construction of public and business buildings, is now finding its way into the construction of churches. The frame work of an Episcopal church now in process of erection in New York City and of a Jewish Synagogue at St. Louis, the latter including a central dome, is composed of structural steel. Some months ago it was recorded that a residence was also being built in New York by this method.

The Grotesque in Carving.

IN glancing at the various buildings in progress in the city and at those recently completed, where carving to any extent has been indulged in, it is a little surprising to find how very greatly the grotesque predominates. We might almost say that there is no attempt made to produce a beautiful face; for instance, on caps or string-courses, wherever there is a face it is sure to be one with a grin or a squint, and though these are perfectly admissible, yet the endless succession of them becomes wearisome. The grotesque is, of course, very easy to draw and takes little time or study, but comparatively few can draw a good face. What a pleasure it would be to have a few to look at, and what a satisfaction to the artist it would be to produce them.

The Establishment of a Museum.

A REMARK was recently made in one of our daily papers that the institutions of Toronto could not be complete until there was numbered among them a museum. A museum is a very important educational factor, and we quite agree with the statement. In this country (and it must be the same in every "new country,") the establishment of a museum is necessarily a very difficult thing. Very few real antiquities or original old works of art are likely to find their way into our collections. Efforts of the most praiseworthy character have been made to establish something of the kind in Toronto, and great success has attended these efforts so far as they have gone. If any one body of educated men can do more than another towards making a museum useful and interesting, that body is the Association of Architects. They must know the immense value as a practical educator of the few casts of Egyptian and Assyrian work that are to be found in the museum of the Ontario Department of Education, and if individual architects would show their appreciation of these things by taking

interest in the collection of photographs, examples of colour decoration, sculpture and so on, and occasionally adding thereto, some gift, however small, a great deal would soon be accomplished and the public interest would be aroused. Students certainly cannot complain of lack of subjects to sketch in winter or whenever the weather is bad. There are in the present collection casts of well-known statues and groups and we have no doubt that permission might be obtained for students to go there with their sketch books and spend a few profitable hours. Might not the Architectural Association interest itself in this matter and thereby accomplish a very useful work?

Derrick Marks in Stone.

We should like to call attention to what seems to be an oversight on the part of both architects and engineers as well as contractors. Why should stone cutters or laborers allow the claws of the derrick which is to raise a heavy stone to grip the stone on the face, instead of at the sides? The marks of the iron claw is visible to-day on the surface of stones in many buildings and will be there for all time. It seems a small matter, perhaps, but it creates an eyesore and could easily be avoided. The worst specimen of the kind is the stonework of the King street subway, where nearly every stone has had a small circular sinking cut on its face, to enable the claw to get a firm grip, and every stone so treated is disfigured for life and the general effect is marred.

Penalty for Black-Listing.

For refusing to obey the command of the trades unions to discharge two of their employees, a firm of contractors in London, Eng., were recently black-listed. The unions posted up throughout the city upwards of seven hundred copies of a poster, having a black border, headed "Trollope's Black List," and bearing the names of the two obnoxious workmen. The firm appealed to the courts, and were granted a perpetual injunction restraining the unions from issuing any additional copies of the poster, and £500 damages for injuries sustained as the result of the copies which had been printed and circulated. A few decisions of this character would do much to check the tyrannical practices to which the trades unions are prone to resort for the accomplishment of their purposes.

Sketching by Students.

We wish that it were possible to impress upon students the immense importance of sketching. Too little attention, by far, is given to this, which ought to be a very important feature in the self education of would-be architects. Nothing impresses a detail on the mind so well as to make a sketch of it, and an intricate detail cannot be thoroughly learned unless it is sketched. To say nothing of the facility in the use of the pencil, the lissomeness given to the fingers, the training of the eye acquired by constant sketching, to be able to draw freehand any subject that chance may present is as important to an architect as fluency of speech to a public speaker. We published last month a measured drawing of an old English castle measuring and drawing from such measurements is the constant practise of students in Europe, to which is added the freehand sketching of the details. This may well serve as an example to our students. A great deal has been said from time to time of the necessity of this kind of thing for students; now is the season when they should put it in practise, and surely one who appreciates his profession will find this work a delightful recreation.

The Omission of Design in Examinations.

The question has been raised as to whether the subject of design should be omitted in examinations of students in architecture, or whether it would not be advisable to curtail examinations on that point for the reason that design cannot be taught. No man who has not "got it in him" by nature, can have it "put into him" by any amount of instruction. The subject occupies an important place in the curriculum of architectural schools, and this argues that it should not be left out in examinations without serious consideration. It is true no one can design unless he has a natural gift, but like all gifts, unless of the very highest order, the "heaven-born spark" requires cultivation, and it is only by study that the gift can be developed. If a man is to pose as an "artist in building" there can be no possible objection to his shewing by examination how far he comprehends the "principles" upon which the art is based, and it is upon the "principles" of the art of design that the examination should be set. A man may, if his genius bends in that direction, design for his pleasure or for the benefit of his clients any kind of conglomerate structure, and if he is a true artist—one who has developed his natural instinct by the study of the art in all ages—the principles of the art will be found in all his work, and there will be in his designs the sense of proportion and the feeling of repose. The questions set or the work asked for at an examination should not be so much a test of artistic ability as for the purpose of ascertaining whether the candidate knows anything of the principles of his art. The scientific or more practical part of an architect's work is getting more and more intricate every year entailing continual study in new methods of construction, new materials and so on, to enable him to keep abreast of the times. Certain new methods or requirements may and probably of necessity must be in the hands of the specialist, but the architect must before long know all about everything that has to be introduced constructionally into his building or that has to appear on the surface and therefore be a matter of design; and in this case it is certain that he needs to have the "principles" of design at his fingers ends for he will certainly spoil his work unless he can apply these principles to every detail.

GURNEY FOUNDRY COMPANY'S EXCURSION.

The fourth annual excursion of the employees of the Gurney Foundry Co., of Toronto, was held on the 27th of June at Lake Erie Park, near Port Colborne. The excursionists, numbering about four hundred, sailed across the lake on the steamer Empress of India to Port Dalhousie, where the train was taken for their destination. At the park an enjoyable afternoon was spent in various games, one of the special features being a baseball match between the Gurney Foundry Company and representatives of the retail stove trade, the latter winning the honors.

Mr. T. B. Alcock represented the company, the president, Mr. Edward Gurney, being unable to be present. Among the architects present were Messrs. Edwards, Brown, Siddall, and Bradley.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

ARCHITECTURAL EXHIBITION.

It has been definitely resolved to hold an architectural and arts and crafts exhibition in connection with the annual meeting of the Province of Quebec Association of Architects.

The principal committees are organized as follows:

General committee—A. C. Hutchison, A. T. Taylor, Jos. Venne, Jas. Nelson, E. Maxwell, J. Z. Resther, F. H. Berlinguet, R. Findlay, A. F. Dunlop, A. Raza, Chas. Baillargé, W. E. Doran, J. F. Peachy.

Reception of Drawings Committee—E. Maxwell, R. Findlay, Jos. Venne.

Arts and Crafts Committee—Jas. Nelson, J. Z. Resther, A. C. Hutchison.

Loan Exhibit Committee—A. T. Taylor, W. McLennan, R. Findlay.

Printing, Advertisements and Reception Committee.—A. Raza, J. W. Hopkins, Jos. Perrault, G. W. Wood, R. Findlay, Jos. Venne.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.

At a special meeting of the above Association nearly all the members were present. Resolutions of condolence were passed at the death of Mr. J. B. Resther. On motion by Mr. V. Roy, seconded by Mr. W. Hopkins, it was resolved:

That the members of this Association have learned with deep regret of the loss they have sustained in the death of the late Mr. J. B. Resther, one of its most devoted members and founders. That the Association presents to his bereaved family its most sincere sympathies, and that a copy of this resolution be presented to the family and to the newspapers, and that communication of same be given to the members of this Association throughout the Province of Quebec.

THE NOTRE DAME STREET BRIDGE.

The conflict between the city and the C. P. R. regarding the construction of the bridge on Notre Dame street, at the east end station, is far from being settled, the superior court having not yet rendered judgment. It will be remembered that the C. P. R. Company were to have charge of the excavation work, but owing to the different manner of interpreting the contract between the two parties, the City Council resolved to do the work, estimated to cost $35,000, awaiting the decision of the superior court as to the meaning of the terms of the contract. The city solicitor has been consulted on the subject, but refuses to make known his opinion before the court judgment.

ARCHITECTURAL TERMS EXPLAINED.

A recent issue of the Brickbuilder contains the following explanation of the various phrases used by architects and not generally used by the mechanic, which may prove beneficial to many. The front, or facade, made after the ancient models, or any portion of it, may represent three parts, occupying different heights; the pedestal is the lower part, usually supporting a column, and its place supplied by a stylobate; the stylobate is either a platform with steps or a continuous pedestal supporting a row of columns. The lower part of a finished pedestal is called a plinth, the middle part is the die, the upper part the cornice of the pedestal or surbase. The column is the middle part, situated upon the pedestal or stylobate. It is generally detached from the wall, but is sometimes buried in it for half its diameter, and is then said to be engaged. Pilasters are square or flat columns attached to walls. The lower part of the column when detached is called the base; the middle or longest part is the shaft, and the upper or ornamental part is the capital. The swell of the column is called the entasis. The height of columns is measured in diameters of the column itself, taken always at the base. The entablature is the horizontal continuous portion which rests upon the top of a row of columns. The lower part of the entablature is called the architrave, the middle is the frieze, while the upper or projecting part is the cornice. The pediment is the triangular face produced by the extremity of the roof. The middle or flat portion enclosed by the cornice of the pediment is called the tympanum. Pedestals for statues erected on the summit and extremities of the pediment are called acrosteria. An attic is an upper part of a building, terminated at the top by a horizontal line, instead of a pediment.

The different moldings in architecture are described from their sections or from the profile which they present when cut across. Of these the torus is a convex, but its outline is only a quarter of a circle; the scotia is a deep concave molding; the cavetto is also a concave and occupying but quarter of a circle; the cymatium is an undulating molding, of which the upper part is concave and the lower convex; the ogee, or talon, is an inverted cymatium; the fillet is a small square or flat molding. In architectural measurement a diameter means the width of a column at its base. A module is half a diameter, and a minute is a sixtieth part of a diameter.

The effect of sunshine was gained in a living room that only had a north light by having the woodwork painted with white enamel, the upper part of the windows set with panes of pale yellow glass and the windows themselves beneath the glass hung with curtains of pale yellow silk.

When will builders understand that brickwork may very well be painted to great advantage? In some districts the bricks, though hard and durable, are of a poor colour, an insipid variety of salmon being perhaps the most objectionable. Two or three good coats of paint finished flat would greatly improve the appearance of buildings erected in such bricks, and the mortar joints may be painted in white or black.

The following is extracted from specifications for the preparation and use of cement mortar for the Sanitary District of Chicago, natural cement being used:—"(a) Measure sand proportion in dry mixing box. (b) Measure cement on top of sand. (c) Overcast twice with shovel, or more often if necessary. (d) Cast dry mixture of cement and sand through No. 5 sieve or screen. (e) Be sure incorporation is fully accomplished before adding any water. (f) Add water at part of wet mixing box remote from screen. (g) Add water slowly and gradually to prevent washing. (h) Hoe dry mixture slowly into water, avoiding any stirring further than to uniformly wet the mixture. (i) Conform mortar mixing to progress of the work so no mortar goes into the wall after having been wet 15 minutes."

interest in the collection of photographs, examples of colour decoration, sculpture and so on, and occasionally adding thereto, some gift, however small, a great deal would soon be accomplished and the public interest would be aroused. Students certainly cannot complain of lack of subjects to sketch in winter or whenever the weather is bad. There are in the present collection casts of well-known statues and groups and we have no doubt that permission might be obtained for students to go there with their sketch books and spend a few profitable hours. Might not the Architectural Association interest itself in this matter and thereby accomplish a very useful work?

Derrick Marks in Stone.

We should like to call attention to what seems to be an oversight on the part of both architects and engineers as well as contractors. (h) Hoe dry mixture slowly into water, avoiding any stirring further than to uniformly wet the mixture. (i) Conform mortar mixing to progress of the work so no mortar goes into the wall after having been wet 15 minutes."

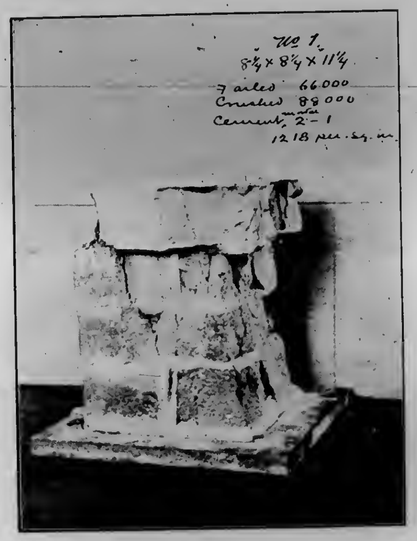
TESTS OF CANADIAN AND ENGLISH BRICKWORK.

CANADIAN architects and builders in common with manufacturers and dealers, have been placed under obligation to the authorities of the School of Practical Science, Toronto, and the School of Technology in connection with McGill University, Montreal, by the series of tests of native constructive materials which in recent years have been successfully carried out in the laboratories of these institutions. As a result of these tests



there is now available considerable detailed information regarding the variety, character and strength of British Columbia timber, Canadian native and Portland cement and Canadian building stones the tests of the latter having been carried out and the results published under the direction of the Ontario Association of Architects.

In a recent number of this journal was published a table showing results of tests by the Public Works Department of Ontario of the absorbent properties of pressed bricks from the various manufactories throughout Ontario. In this number are given illustrations and some particulars of tests of common brick conducted by Mr. C. H. C. Wright and his assistants at the School of Practical Science, Toronto, at the commencement of the present year. The bricks employed in the tests were procured from four different brick yards in the neighborhood of Toronto, viz., the Kingston road, the Humber, Yorkville and Carleton. Before being built into piers, the bricks were individually tested for absorption by being immersed in water for thirty minutes.

The piers were built by a skilled bricklayer, who also provided the lime mortar, which consisted of 4½ yards of Bloor street coarse sand to ten barrels of lime, this being about the proportion of two parts sand to one part lime. The cement mortar was mixed in the proportion of three parts sand to one part of good Portland cement.

The piers were built and laid aside to harden in the mechanical laboratory of the School of Practical Science, in a temperature which averaged about 60° Fahrenheit, and were prepared for the test as follows: A thin mortar of neat cement was spread on a smooth cast-iron plate, and the pier placed upon the mortar and left until the cement hardened. The bottom bed was then trimmed off flush with the sides, the pier placed on the testing machine, and a layer of neat Portland cement mortar was placed on top, the pier was slid under the head of machine, and the head was brought to its bearing while the mortar was yet soft. This method ensured two parallel beds and gave a uniformly distributed stress on the pier. The load was applied slowly and continuously, until complete failure of the pier occurred.

The results of the tests are as follows:—

Pier No. 1.—Common brick, 4 courses; dimensions, 8½ × 8½ × 11¼" high; ult. strength, 88,000 pounds; cement mortar, 2 to 1.

No. 2.—Common brick, 6 courses; dimensions, 8½ × 8½ × 16¼" high; ult. strength, 78,000 pounds; cement mortar, 2 to 1.

No. 3.—Common brick, second quality, 5 courses; dimensions, 8½ × 8½ × 14¼" high; ult. strength, 70,000 pounds; cement mortar, 2 to 1.

No. 4.—Common brick, first quality, 8 courses; dimensions, 8½ × 8½ × 22" high; ult. strength, 128,000 pounds.

Our knowledge of this important subject is further augmented by an elaborate and carefully conducted

series of tests of English brickwork carried out under the direction of the Science Standing Committee of the Royal Institute of British Architects, the results of which have recently appeared in the British architectural journals. Strange as it may appear these tests are said to afford the only accurate information available upon the subject. The method adopted was similar to the Canadian one, viz., to first test the individual bricks and afterwards test piers 18 inches square and 6 feet in height, composed of similar bricks, some built in mortar and some in cement. A specially designed testing

machine capable of exerting a pressure of 500 tons was employed.

The brick piers to be tested were built upon wrought-iron plates, 2 ft. 6 in. × 2 ft. × ½ in. thick, placed upon temporary lines of rails 140 feet in length, laid to 16 in. guage. The piers, standing on the iron plates, were drawn along the rails by a suitable crab and winch, so that all unnecessary handling of the piers was carefully avoided and risk of fracture thereby entirely obviated.

The following varieties of bricks were used in building the piers:—

1. London stocks from Sittingbourne, Kent.
2. Gault from Burham, Kent.
3. Leicester red from Elliston, near Leicester.
4. Staffordshire blue from Rowley Regis.

Each pier was constructed in duplicate, in lime mortar and cement mortar, so that the total number of

FIG. 3.

piers to be experimented upon was 32, that is to say, 16 for testing at the age of 3 months, and 16 for nine months' tests. The piers were, with one exception, 18 in. × 18 in. and 6 feet high, or as near those dimensions as the particular kind of brick would allow; the exact dimensions are tabulated in the report.

Four bricks of each class were carefully tested by Professor Unwin at the Central Technical College, and the following results were recorded for the respective crushing loads.

Description.	Crushing stress, tons per square foot.	Mean strength, tons per square foot.
London Stocks ..	60·76 — 94·6	84·27
Gault	166·9 — 197·6	182·2
Leicester red ..	311·4 — 391·4	382·4
Blue Stafford ..	564·8 — 788·0	701·0

It is also recorded that some of the bricks were too strong to be crushed as whole bricks in the 100 ton testing machine at Kensington, and, therefore, half bricks were used. With the exception of London stocks, which are roughly made, and, therefore, not capable of being very neatly divided, it appears that bricks tested as half-bricks show about 25 per cent. less resistance per square foot than when tested as whole bricks. A tabulated statement is given in the report to illustrate this point.

The lime and cement mortars used in building the piers were also carefully tested, and the compressive strengths ascertained. The results are summarised as follows:—

Lime briquettes, composed of 2 of sand to 1 of lime by measure:—

Strength at 4 weeks 6·68 tons per square foot.
" " 12 " 8·73 " " "
" " 24 " 15·72 " " "

Cement briquettes, composed of 4 of sand to 1 of cement by measure:—

Mean strength at 4 weeks, 31·45 tons per square foot.
" " 13·7 " 48·52 " " "
" " 24 " 56·15 " " "

The above-named briquettes were formed with the standard sand normally employed in testing cements and other similar materials. It is a pure siliceous sand, obtained from Leighton Buzzard. The actual sand used in building the piers was not so pure in quality, having a rather large proportion of earthy matter, ranging from 0·14 to 0·96 per cent. in the several samples analysed. The mean strength was, therefore, lower, being, for the cement briquettes, 29·00 tons per square foot at the age of 24 weeks.

Analyses of the lime and cement mortars were also made by Mr. W. J. Dibdin, chemist to the London County Council, from material taken from the debris of the piers after they had been experimented upon.

The crushing of the piers was carried on in December last, the first pier being crushed on the 9th of that month as an experimental trial of the testing apparatus. Owing to the large-sized valve on the hydraulic ram, the water pressure was admitted too freely, and the pier was crushed too quickly for accurate results to be obtained. It has consequently been rebuilt for further trial. Before the next piers were experimented upon, careful alterations were made to the ram valve, a fresh pressure gauge was introduced, and a modification was made to the testing frame to obviate a slight concavity in the head girders. The apparatus was then found to be in proper order for testing the remaining piers. Detailed descriptive tables are given of the results obtained by crushing each pier, and they indicate the manner in which the experiments were carried out.

A summary is given of the results obtained on the 16 piers tested, which may be briefly tabulated as under:—

No. of Pier.	Description of Brick.	Age.	Commencement of failure.	Final collapse.
		Weeks.	Tons per square feet.	Tons per sq. foot.
1	London Stocks in Mortar	17·7	—	—
2	" " "	18·3	4·18	10·41
3	Gault .. .. "	18·3	5·00	21·82
4	" .. .. "	18·8	6·16	22·03
5	Leicester Red .. "	19·1	13·20	20·03
6	" " "	18·6	16·11	31·55
7	Staffordshire Blue "	18·6	22·43	66·22
8	" " "	19·4	21·42	79·39
9	London Stocks in Cement	21·1	7·22	16·03
10	" " "	21·0	5·72	13·83
*11	Gault .. .. "	21·0	6·98	17·98
*12	" .. .. "	20·5	7·08	17·51
13	Leicester Red .. "	22·1	17·87	67·36
*14	" " "	21·7	21·82	49·54
*15	Staffordshire Blue "	21·7	20·45	84·47
*16	" " "	22·7	16·91	61·14

The piers marked *, when crushed, were found to have been partly constructed with portions of stock bricks for filling in, instead of the proper material for the respective piers. It has, therefore, been considered desirable to re-construct these piers so that the final results may be absolutely accurate. From a practical point of view, says the British Clayworker, it is, perhaps, not greatly to be regretted that such an "accident" should have happened, for the Institute will be in a better

position to gauge the effect of the introduction of extraneous material in the harder brick piers. It is, unfortunately, not an uncommon experience in dealing with hard bricks, to find that some workmen make no endeavor to cut closers, but substitute bricks which can be more readily manipulated. This defective work would be almost entirely obviated if brickmakers would produce king and queen closers of all the harder varieties of bricks.

An interesting series of photographs was taken of all the piers under different stages of compression, from which some of the most instructive and typical forms of failure may be studied. At early stages of pressure, the mortar and cement joints begin to fail—they squeeze out, and portions drop off. This is followed by the cracking of some of the bricks, and spalling off at the angles. Longitudinal seams, in most instances, were opened out in a line with the

Fig 4.

vertical joints or closers, and finally, in many instances, the piers bulged out on all sides and collapsed.

The differences in the behaviour of the piers while under compression were accurately noted in each case.

It is stated that, "all through the series it was evident that the vertical line of joints formed by the closers was a plane of weakness, and it was generally at this line that the serious cracks first showed themselves." In the discussion which followed the reading of the report, Professor Unwin said: "If the structure is one that has special vertical planes of weakness, like the joints in a pier which has not been built very long, then the crushing load develops vertical fissures, due to the tension acting horizontally." We may point out that in the brick piers experimented upon by the American Institution of Civil Engineers at Watertown Arsenal, the normal type of failure was this vertical splitting of the pier, as in nearly every instance longitudinal cracks and seams were opened up. In the American examples, so far as we can judge from the sketches and diagrams appended to the Official Report, no closers were used, the bricks in all cases being whole bricks, so disposed as to break joint. Various types of bonding were also employed; in some instances as many as five or six courses had the vertical joints in one plane, the alternating five or six courses breaking joint in another plane. Yet, even in these cases, the same vertical fissures appeared, emanating from the vertical planes of weakness. It seems, therefore, fair to infer that there is little evidence to show that the closer method of bonding is more defective than the whole-brick bond. Moreover, as the American piers were much older than any of the piers tested by the Royal Institute of British Architects, the age ranging from 15 to 24 months, the newness of the pier does not, in this respect, appear to be of the importance suggested by Professor Unwin.

TALKS ON HOUSE PAINTING.

It is doubtful whether the average carpenter and builder or general contractor gives the subject of painting the attention it deserves, says Mr. Seymour Jennings, and this is especially the case with those who carry on business in a comparatively small way. If the amount of painting to be done forms a very considerable part of the work, as in the case of repairs, they will, as a rule, either decide not to tender at all, or else will obtain a tender from a painter as sub-contractor. This is all very well for the painter, but the builder, of course, has to make his price somewhat higher, to cover his own trouble, and so he stands but little chance of getting the work.

In new work, as in old, the painting is an important item, and it behooves the contractor to see that it is executed in the most economical manner possible. Now there is no part of work in the building trade that is so easy to "scamp" as the painting. If the brickwork is wrong, or if the woodwork is inferior, it shows itself at once, and besides, as far as the actual structure itself is concerned, the district surveyor or his equivalent will look after that, to say nothing of the architect. But when it comes to the paint the case is very different. The local authority, whoever he may be, doesn't care twopence about it, and in ninety-nine cases out of a hundred the architect himself knows little concerning it—in fact, excepting so far as the actual appearance of the work when finished is concerned, he as a rule has no idea whether it is good or bad.

These facts must be borne in mind by the carpenter who gives his work out to a sub-contracting painter to do. Unless he has made a study of paints and painting, he is in the painter's hands almost entirely. Not that I have a word to say against painters as a class; considering the temptations they have to contend with, they are, I, think, in integrity not a little above some other trades I could mention. The point that I do want to insist upon is, it never pays to scamp the painting. The defects will soon become obvious. Suppose, for instance, that you have some work to do at a low price, and, in order to make it pay, it is impossible to use the best materials. You must economize somewhere. Very well, but don't do it to any extent in the painting. If you use, for instance, a common resin varnish at a few shillings a gallon, and after a few months it cracks in all directions, what sort of a reputation do you think you will get for yourself? I do not mean to say you should use 20s. varnish, but do use fair quality, honest goods.

If I have convinced you that it always pays to let the painting be done as well as possible, within the price to be paid for the work as a whole, it will, of course, follow that if you do give it out, you should, under no circumstances, let it to any one who is not known to you to be an honest, straightforward man of his word. Again, if you decide to do the work yourself, you should for your own protection, only deal with a first-

class house, who will sell you only good materials. By "first-class" I do not mean necessarily a large concern, but one upon which you and others may absolutely rely. The importance of this will become apparent to you if you consider for a minute. If you go to your timber merchant to buy some timber you are very unlikely to be deceived; you know what you are buying. If you are a family man and go to the butcher's to purchase a joint of meat, it is quite unlikely that he'll "have you" isn't it? Unless, indeed, in selling foreign-killed meat as English. But when it comes to paint material, how do you know whether the white lead is not half chalk, the linseed oil largely composed of resin with, perhaps, a little mineral oil added? You don't know, or at least, very few carpenters and builders do. Why, even the turpentine may be largely adulterated with benzine, and as for the colours—I have many times come across so-called vermilion that consisted wholly of red lead toned up to the proper colour with the dye recene; and I have known a green sold containing over ninety per cent. of barytes, an adulterant that is absolutely valueless for staining or colouring purposes, for the very simple reason that it has no colour.

I want to consider some of the methods by which you may economize. One, and perhaps the most important, item is the prevention of waste. Many workmen are allowed to get into slovenly habits and waste a good deal of material; and this is especially the case with dry colours, most of which are quite expensive. The most economical colours to use, by the bye, are those ground in oil. There is very little waste with them and they save time. But the great secret of economy in the paint department is to engage a good, smart foreman, one who will get the men into good habits and keep them so, and who will keep a watchful eye to see that they not only take care of the material, but that they keep their brushes and tools in good order. Pay such a foreman a few shillings more a week, if necessary; it will be money well spent, I assure you.

You have, doubtless, heard of the old story of the New York builder and his hod-carriers. In any case, it will bear repetition. The custom "on the other side," as here, is for the hod carriers to go up and down the ladder in regular order, every man in his proper place. For one man to get before or behind another would be an awful thing. Well, the builder of whom I speak noticed that the carriers were going up and down the ladders very slowly, much to his disgust. He tried all means to make them go faster, including, I am afraid, some not very choice language; but it was no use. Presently an idea occurred to him. He picked out a smart young fellow and took him into his confidence, promised him twenty-five per cent. more wages, and put him at the head of the gang. Of course this leader exerted very nerve to get up and down quickly, and as the whole gang was compelled to follow him, the "boss" got somewhere about twenty-five per cent. more work out of all the men for his expenditure of twenty-five per cent extra on one of them. So take my advice. Have a smart foreman who will look after your interests, not one, though, on any account, who cannot get along well with the men. There is all the difference in the world between getting a fair amount of work out of a man and being a nigger-driver. The clever foreman knows where the line should be drawn.

Another thing do insist upon the men being properly clad. I know a painter who insists upon every workman bringing clean overalls every Monday morning. He told me that the rule was much objected to at first, but he insisted, and now the men go out to a job a credit to their employer and to themselves. And if you do repairing work, do, as you value your future prospects, have everything cleared up after you. Leave the place neat and tidy. It will cost you a shilling or so more, but take my word that it will not be money thrown away. Have you ever considered the bearing that women have on the repairing part of your business? True, it is the gentleman who pays the bill and who assents to the work being done, but it is the lady who has to put up with all the trouble and fuss, and it is she also who you should aim to please in ninety-nine cases out of a hundred. Now, perhaps most likely, in fact—you recognized all this years ago, and always make a practice of having the colours of paper and paintwork suit her taste. Well, you do right. Never mind about the man who pays the bill. She'll know how to deal with him if she's an average wife, because if she is that she will possess a full share of that valuable quality, tact. But don't spoil all your efforts to cultivate her goodwill by leaving a lot of rubbish around.

Now as to materials. Do not use ready mixed paints; they are not made for painters. They are intended for the "everybody-his-own-painter" sort of a man—the man who finds time hang so heavily on his hands that he will cheerfully spend about three times as much on labour (certainly its his own) and bad paint in painting a job than would pay for the work to be properly done by a qualified mechanic. You know the kind of man; he is closely related to the gentleman who builds himself a summer house of a nightmare design, and who uses up about three times the amount of timber required, spoils a complete set of cheap tools (which is not to be regretted), and smashes his thumb half a dozen times or so during the process, and all in order that he may have the pleasure of doing what the carpenter would have done for him at half the cost and then made a handsome profit.

I have said before, use good materials. Of course you know that there are various grades of white lead. There is "Genuine," "No. 1," "No. 2," and so on. The genuine is genuine—that is to say, it is strictly pure hydro-carbonate of lead i.e., white lead proper. The other grades are cheaper and contain more or less whiting, barytes and other materials. For certain work they will do well enough, especially for that which is not exposed to the weather. A friend of mine had some years ago the job of redecorating a large school room. The walls and ceilings were to be painted in lead and oil, and the work was to be finished by a certain date under heavy penalties in case of failure. Work seemed to pour in that week, and, as a consequence, the school work was to be delayed. On the day before the work was to be completed the ceiling had not been touched. In the morning one coat was given it, and my friend calculated that by two o'clock the following morning it would be quite dry enough to take the second coat, so he arranged that some of the men should work all night. About one o'clock he went to the job to take a final look at it before going home, and to his horror found that it had been discovered that there was only enough white lead to do about one-third of the work. There was plenty of oil and plenty of turps. The only thing in the paint material way on the premises was a lot of putty. So he gave orders at once to have this beaten up with the lead, added a liberal amount of oil and turps, and finished the job. He assured me that the work stood as well as any he had ever done. Of course, what he had done, in fact, was to make his paint very similar to, say, No. 2 or No. 3 white lead. Putty, of course, is simply whiting ground in linseed oil, and by adding the whiting to the lead, and giving the mixture a good binder in the shape of pure linseed oil, he had obtained a good paint—that is good for the particular purpose—at a very low cost.

MANUFACTURES AND MATERIALS

"COPPER."

The following is an abstract of a paper read by Mr. Nelson Dawson before the Architectural Association of London, Eng.:

In talking about metal, its uses and design, the metal-worker, unconsciously perhaps, divides the subject in his own mind into three parts—cast, forged, and sheet. Here are the three different treatments to which nearly every metal can be subjected, and the three processes that the designer can take advantage of in thinking out his design. These practically are also the three different trades into which metal workmen are divided.

It is not until we come to look closely into the thing that we see how widely apart these three branches lie. One may not realise at the first glance that under the heading "cast" nearly all statuesque and sculptors' metal-work must be done; and if we do not admit that it "must" be cast, at least we know that it always has been so up to the present, except in very early days.

For wrought work we may take, as an example, the Eleanor grille in Westminster Abbey, that monument of twelfth-century skill in ironwork.

For treatment of metal in sheet we might instance the elaborate figure-compositions of Cellini's time, that have since then been used to cover shields with, or to beat up a dish for an altar, or to put some repousse' ornament on a cup or other plane surface. Here, indeed, are three very different crafts so widely apart that really we should not wonder that they have become so much split up and separated, or that all metals are not capable of receiving all three treatments satisfactorily. Thus, with copper, we find it is practically useless for casting; while in forged work we can with difficulty recall anything in this metal, so we are left with sheet, and here really lies the strong point of copper.

The kindliness of copper under the hammer in practice is a constant surprise; with care one is able to do almost anything with it—to bump it up into relief, and then, if it is wrong, to hammer it all flat and begin again; to take a flat piece, and hammer it first into a cup-shape, afterwards drawing in the top and lengthening it upwards until the original piece of sheet-copper is a vase with oval body and long narrow neck. A metal-spinner of much experience said that in their trade the most difficult thing to do was the ordinary stethoscope that doctors use. But a good coppersmith would not make any difficulty about such a shape if he had a good bit of copper to do it with. Formerly the common jelly mould was the triumph of the craft, and it is easy to understand that to make a shape with many pinnacles and castellations from flat sheet, keeping a fairly even thickness and never tearing open the metal, took some skill (one uses the past tense because, probably, being such a very fine sort of craft, it is by this time obsolete, and put aside in favour of a mechanical process, such as stamping).

Repousse' has come to be the general term for all ornamental work raised on sheet-copper by the hammer. The prefix "re" probably means "back," so that it implies that some part of the metal is beaten back. It really hardly matters if, to gain the relief, one beats up the design from the back, or beats back the background in front—pretty much the same end is reached.

In beating up small ornamental work in copper, especially when it is as small as silversmiths require, it is put down on a cement made of pitch and other ingredients. This is melted every time the copper is put down, and, besides holding the metal tightly, offers a slightly yielding material against which to hammer. If, when the copper is on the pitch, we take a punch and make a straight line—indented of course—that line will come out on the face of the metal as a clean, sharp line. If, however, we do not put the copper on to any cement at all, but make the indented line on it, as it lies on the wooden bench, it produces a very different effect on the face side. Now the line shows indefinitely, and, instead of the metal being raised just where it was struck, the surrounding part is dragged up too. If an effect were desired between these two extremes, one should place the copper on a half-way material, such as stiff clay or modelling wax. The result of the beating would also be half-way—neither too precise a line nor too blurred.

It will be seen that these three courses are likely to give a considerable range, especially where the metal-worker has some artistic capabilities; but the usual way, which is generally the worse way, is to first trace on the face side of the copper the whole design, with what is practically an incised line, and then slightly bump it up here and there from the back. This is the cheapest and readiest way of getting an effect. But to get the best quality out of copper or any other metal with the repousse' treatment, let the face-side have the least possible amount of work—none at all, if it can be helped.

This point is an all-important one architecturally, for this reason: That where ornamental copper would be used in a building as a decorative panel—a tablet with lettering otherwise—it should "carry," as a sculptor says—that is, the design should look clearer at a little distance off than it does close to. A design which is clearly and sharply cut and looks very well close to will not show to advantage at a distance, will not "carry," in other words, while a design that looks somewhat blurred and indistinct close to becomes quite sharp and clear ten yards off it "carries" exceedingly well. This is one very good reason for putting all the work possible on the back of the metal, leaving it somewhat blurred in front, and not "finishing" it, as they say, by chasing and putting a clean hard line around everything.

One objection that is made regarding copper when used for decoration in a house is that it requires cleaning, or it loses its chief beauty. Well, there is some truth in this, but it is not altogether correct. In the first place, if it be required to keep its own colour, it can be lacquered; and this, if judiciously done, will last a very long time, and is both easy and cheap to renew when necessary. But copper that is not lacquered—simply left and dusted in the ordinary way by the housemaid when the rest of the house is dusted—will take a most delightful color in time.

There is a whole range of colours that once produced on the copper are not only themselves permanent, but act as a varnish in preventing an action of the atmosphere.

The importance of this fact showed out recently in the case of a memorial-tablet in a church which was

desired to be of copper, the objection being that when the immediate friends had passed away, it would become uncared for and soon reach the dingy state, a condition that the more familiar marble never reaches. It seems difficult to find a metal that would do any better than copper, which was wanted, but with the aid of such an artificially-produced patina, the difficulty is removed, and there is no reason why copper should not be used. For any case where an inscription or lettering in any form is wanted, it may be said that no other metal opens out such chances as copper, especially if treated in an artistic manner, provided, of course, the design and execution is not left to the tender mercies of the usual commercial person.

One can only refer to the lamentable state that mural brasses have reached in our time, and suggest that the artistically treated copper offers an escape from such terrors, especially if the tablet be within reach of an occasional duster, giving the slight amount of polish that makes the use of lacquer or other preservatives unnecessary.

One other treatment of copper must be noticed before finishing, and as artists we shall feel it to be treading on unholy ground—electrotyping. Sometimes one thinks that this must be a fine process and a nineteenth-century blessing, while the next electro one comes across the whole thing is condemned bag and baggage. A clever mechanic will turn out in electro a copy of a repousse dish that an expert could not tell from the original, unless he looked at the back. This is a thing to be thankful for, this tell-tale back of the electrotype, otherwise there would be no telling at all, so faithfully does it reproduce every mark, even touch of the hammer or chisel. It is interesting to know what is going on around us, and it may not be out of place to relate a little incident that occurred recently. In the workshop of a clever electrotyper a specimen of work was brought in to show. It was a small electric-light table-standard about 9 in. high, of interesting design, and apparently highly chased, in copper, with a good chocolate-brown patina, and mounted on a small oak plinth. "Now this," said he, "is electroed from a fine old Sheffield plate candle-stick in the South Kensington Museum, and we have an order for a quantity. We have acquired the right to reproduce the things in the museum, and, with our skill in this line, there is nothing that we shall not be able to copy."

Now, frankly, if I had seen this piece in a shop I should not have been able to tell how it had been made, because it had been electroed in two halves and soldered up, so that the back could not be seen, and on the face only gave the evidence of highly chased work and most careful finishing.

One may say, if this has exactly the appearance of the correct thing, it must be as good. Most plausible, but most weak! There is often a sorry mind behind a fair face, and the fact that you can mechanically reproduce a good thing a hundred times, makes it a hundred times worse. A good piece of copper or any other metal work, on which an artist has spent time and care, will always be valuable; and equally the most exact reproduction of it, especially by any mechanical means, will always be valueless. Seriously and calmly, this form of copper work is the only one that may be called unlawful, and if we do not leave it altogether alone, it should only be used for the commonest purposes.

We have now considered some of the good points and some of the bad points of copper, and the question naturally arises, To what use can this metal be put with advantage to-day?

Well, externally, and except in the case of roofing, copper is not much used. There has been a mild desire to cover the door of a church or mansion with it occasionally; in the case of the former with repousse work, which we may imagine as capable of having a very rich effect. Sometimes one sees the name of a tradesman in high-relief letters in copper or a name plate by a door, in both of which positions they seem to get well rubbed, and invariably catch the eye as we pass. In one or two cases sheet copper has been largely used, in conjunction with wood-work, in the decoration of big West-end public-houses; and although here it looks applique and cheap, that is not the fault of the copper.

It may be well to take this opportunity of saying how difficult, but how important it is, so to use sheet copper, or any other metal, that it does not look thin and papery, and as if cut out with scissors. Of course sheet-metal, unless of some thickness is frequently cut into shape with shears, but if this is apparent when the work is finished the effect is disastrous. All the durable and hard qualities of the metal seem to disappear, and the thin, fragile undurable character asserts itself unpleasantly. For a glaring instance of this misuse in sheet-metal, though in iron, we have only to turn to the much-vaunted iron railing from Hampton Court Palace, in the South Kensington Museum, reputedly by Huntingdon Shaw.

One would not be understood to mean that sheet-metal must be made to look like cast, or any other form of metal, only equally it must not be made to look like paper. If any metal-work looks thin and poor, not solid and strong and metallic, then the designer is no artist, and the workman no craftsman—both have wasted their time and chance. Beyond these one or two things, then, one does not see copper used externally; though, at least, wherever sheet-brass is used, there also certainly sheet-copper may be used. Indoors it is different, especially in domestic work. For a good, comfortable, homelike, and cheerful appearance in drawing-room, dining-room, or kitchen, one may safely say copper cannot be beaten. Near a fireplace, and kept bright, it has a cherry glow that rivals the fire itself; the mere fact alone of its being kept so bright is a constant and recurring announcement of housewifely attainments.

There is hardly any interior metal-work that, if one desired, might not be done in copper, saving, perhaps, poker and tongs; and even the former of these I once saw made out of a huge copper bolt of some old Navy ship. Hinges, too, one would not use it for, as it would wear too quickly; but we can use the gun-metal alloy where the actual wear and tear comes, and rely on our old friend for the ornamental part.

For finger-plates, a handsome set of door furniture in bright copper will do more to redeem a drawing-room from depression than the most gorgeous wall-paper, and the sparkle of electric lights in copper reflectors and copper stands will be only second to gold itself.

To-day, no lady who had any self-respect could live for a single day if she had not a more or less ancestral copper coal-scuttle, while two or three years ago, to be without any equally ancestral warming-pan hung on the drawing-room wall was almost a punishable matter.

STUDENTS' DEPARTMENT.

C. A. & B. COMPETITION.

We had expected to be able to announce in the present number the decision of the judges in the above competition. Owing, however, to the absence on their holidays of some of the members of the Ontario committee, it has been found impossible to do so.

The report of the committee appointed by the Province of Quebec Association of Architects has been received, but will be held over for publication in our August number simultaneously with the report of the Ontario judges.

MAXIMS FOR DRAFTSMEN.

The power of shading rightly depends mainly on lightness of hand and keenness of sight; but there are other qualities required in drawing dependent not only on lightness, but steadiness of hand; and the eye to be perfect in its power, must be made accurate as well as keen, and not only see shrewdly, but measure justly.

Nearly all expression of form, in drawing, depends on your power of graduating delicately; and the graduation is always most skillful which passes from one tint to another very little paler.

In darkness of ground there is the light of the little pebbles or dust; in darkness or foliage, the glitter of the leaves; in the darkness of flesh, transparency, in that of stone, granulation; in every case there is some mingling of light.

An entire master of the pencil or brush ought, indeed, to be able to draw any form at once as Giotto his circle; but such skill as this is only to be expected of the consummate master, having pencil in hand all his life, all day long, hence, the force of Giotto's proof of his skill.

Ruskin.

COMPETITION CONDITIONS.

The British Architect suggests the following as being lines upon which architectural competitions might be successfully and satisfactorily conducted:

1. There should be two trials. This we still think the better plan in view of the past history of competitions. But we do not see the slightest necessity for the cruel waste of competitors' time and efforts such as usually results.

2. The first competition should be open to everyone over the age of 25.

3. There should be no charge whatever for the conditions of the competition.

4. There should be nothing required beyond plans, one or two sections, one main elevation and two monochrome perspectives, each taken from a given point and of fixed size, and arranged with some reference to the laws of perspective.

5. There should be three fixed premiums, to be paid down outright to the three best of these designs.

6. Out of all the first competitors, six should be selected to compete finally.

7. Each of these should receive a reasonable (not a large) honorarium for preparing elaborated designs, which should follow the lines of their previous ones.

8. The best of these six should be appointed architect.

9. The authorities should agree to leave the decision in the hands of three experts; one to be the city surveyor and the other two artistic practising architects.

EARLY ENGLISH WINDOWS.

Early English glass paintings are remarkable for the intensity, vividness and richness of their colouring, for the strength and boldness of their outlines, for the height, spirited action, and classical air of the figures, and for the form of the foliage used in the patterns. The earliest foliage partakes of the shape of the Greek honeysuckle, like the ornaments of Norman architecture; the latter resembles the trefoil-leaved scrolage so common in Early English sculpture. The richest windows of this style (and which are therefore more rich than any other windows) are the medallation and the Jesse. The medallation window generally has a deep border running entirely round the light. The enclosed space is principally occupied with pictures of simple design, each represented on a panel, having a well-defined border and a stiff coloured ground. The interstices between the panels and the border of the window are filled with ornamental patterns. Very little white glass is used in the windows, and the figures, though strongly shaded, are so little relieved that when seen from a distance the whole window presents the rich, variegated, and somewhat confused appearance of a turkey carpet, to which they have often been likened. The Jesse window, although as rich, is seldom so confused as the medellation window, owing to its design being simpler and better defined. The figure and canopy window, of which there are some splendid remains scattered about Canterbury Cathedral, is less mosaic in its colouring, the figures being much larger than those in the medallation and Jesse windows, which occasions greater breadths of color to be used in the draperies. Yet these windows are as intensely coloured as the others. Their canopy work exactly resembles that in the illuminations and sculpture of the time. The white pattern windows are of a rich sea-green hue. In general their design consists of, as it were, a series of panels laid one over the other, each panel having a separate pattern painted on it. The ground of the pattern is most commonly cross hatched with thin black lines, but this cross hatching is not unfrequently omitted in windows occupying a great height from the floor. Some pattern windows are composed of ornamental quarries. Most of the white pattern windows have deep borders richly coloured like those of medallation windows, and some, as at Stanton Harcourt, are further enriched by the insertion of coloured pictures represented on panels. It is clear that Early English windows owe their magnificent effect to the material of which they are composed. The pot-metal glass is generally deep in hue, but being very irregular in its tint. The white glass, which is usually of a rich sea green colour, is also very irregularly blown, and the ruby glass, except some pieces which seem to have been cut near the extremity of the sheet, is as streaky in its appearance as if the colour had actually been laid on with a brush. It is to these accidental irregularities in hue of the glass that the vivacity of an Early English window is chiefly owing.

In painting buildings that are used to contain articles of an inflammable nature, the painter would do well to suggest the use of a fireproof paint, and while one would think that paint must always burn easily, paints may be obtained that are absolutely uninflammable, one of the best known of these is Asbestos paint, which effectually checks fire in its incipient stage.

THE LATE MR. WILLIAM HASKINS, C. E.

A long and useful life was terminated on the 5th inst., on which date occurred the death of Mr. William Haskins, C. E., the well-known City Engineer and manager of the Waterworks Department of the city of Hamilton. Early in the morning he was afflicted with a stroke of apoplexy, from the effects of which he never regained consciousness, expiring at 5:30 o'clock in the afternoon.

Deceased had been attending to his duties as usual up to the previous Saturday, although for the past two years he had not enjoyed the best of health, and last spring visited a health resort in search of restitution. This he regained in a slight degree only. Of late the affairs of the department over which he had charge have been unusually onerous, necessitating his closest attention.

By his death the city of Hamilton loses an efficient and valuable officer, and one who during his many years

The Late Mr. Wm. Haskins, C. E.

of service exercised his executive ability in an eminently successful manner.

Mr. Haskins was born at Coolkem Hall, County of Wicklow, Ireland, on May 29, 1828, being therefore in his 69th year. He was a son of Abraham Haskins, who came from England and settled in the county of Wicklow. His mother was Margaret Fitzmaurice, daughter of Colonel Fitzmaurice, her father and three brothers being either military or naval officers. He was educated in Dublin, Ireland, where he studied his profession of civil engineer at Trinity College, under Sir John McNeill.

In 1852 deceased came to Canada and obtained a position as assistant engineer on the survey and construction of the Great Western Railway, and afterwards, in 1856, was appointed City Engineer of Hamilton, which position he filled until his death.

In 1861, when the city took over the waterworks from the Board of Commissioners, the duties of manager were entrusted to him. He was not only manager of the engineering, construction and operation of the waterworks system, but financial manager as well, having full charge of the collection and remitting of rates, etc. About 10 years ago these duties were transferred to the tax collector, but Mr. Haskins continued to be city engineer and manager of the waterworks. He was a man of large experience and knowledge, and a thoroughly efficient engineer and public officer. Perhaps his greatest work for the city was the management of the Waterworks Department, which he brought to a high state of efficiency, and with every detail of which he was conversant. Quite recently he prepared a number of plans, minutely describing the whole system, in order that at his death the system might be preserved. His ability was recognized outside of Hamilton by the frequency with which he was called on to advise other corporations contemplating important improvements.

He was a member of the Royal Society of Engineers of England, an Ontario Land Surveyor, and a member of the Society of Civil Engineers of Canada. He was also a member of the Masonic fraternity. In religion he was a member of the Church of England, and in politics a Conservative.

In 1852 Mr. Haskins married Catherine Murray, daughter of Mr. Hugh Murray, of the county of Carlow, Ireland, a gentleman of Scottish ancestry. He leaves a widow and five sons, Messrs. William Fitzmaurice, of Dunnville; Frederick H., of Toronto; Raymond and Gerald, of Hamilton, and Thomas Fitzmaurice, of Dunnville.

His funeral was attended by the mayor and aldermen of the city and the civic employees in a body, and by a very large number of private citizens.

HEATING AND VENTILATING BUILDINGS.

In a work on heating and ventilating buildings, Prof. Carpenter says the most effective location for the air inlet is probably in or near the ceiling of a room, although authorities differ much in this respect. The advantages of introducing warm air at or near the top of the room are: first, the warmer air tends to rise and hence spreads uniformly under the ceiling; second, it gradually displaces other air, and the room becomes filled with pure air without sensible currents or draughts; third, the cooler air sinks to the bottom and can be taken off by a ventilating shaft. So far as the system introduces air at the top of the room it is a forced distribution and produces better results than other methods. When the inlet is placed in the floor or near the bottom part of the walls it is a receptacle for dust from the room and a lodging and breeding place for microbe organisms. In the ventilation of large buildings the inlets can usually be located in the ceiling, especially if the lighting be done by electricity or in some manner not affected by air currents. The outlet for air should be as near the bottom of a room as possible, and it should be connected with a flue of ample size, maintained at a temperature higher than that of the surrounding air, unless forced circulation is in use, in which case the excess of pressure in a room will produce the required circulation. These conditions should lead us to locate vent-flues on the inside walls of a house or a building, and where they will be kept as warm as possible by the surrounding bodies. If for any reason the temperature in the flue becomes lower than that of the surrounding air, the current will move in a reverse direction and the ventilation system will be obstructed. The conditions as to the size of the outlet register are the same as those for the inlet; the register should be of ample size, the opening should be gradually contracted into the flue, and every precaution should be taken to prevent friction losses.

THE BUILDER

Taking Quantities.

In taking measurements where the work is done by the yard, as in painters' work, hardwood finishing, kalsomining and plastering, it is always the best to use a tape-line, then all the breaks, quirks and mouldings can be measured and properly credited. In measuring painting this is very important for running a line around all the corners and quirks of moulded panels adds a large percentage to the total amount, and where the work is piece work, by the yard, the workman is entitled to the full measurement. If the exterior of a house is painted at so much per yard, and the building is a frame one and sided in the ordinary manner, the painter is entitled to payment for the edges of the siding or clapboarding, which, in a building, 24 feet high, would make quite a difference in the result. Twenty-five feet would require forty-eight tiers of siding, and each tier would add one-half inch of surface measurement, or twenty-four inches to the whole height. Let us suppose the building to be fifty feet long, then we should get 100 more surface feet than the face of the building would measure, which would make a little over eleven yards, an item worth looking after. At a meeting of the Master Painters and Decorators of the United States, in Baltimore, some time ago, a schedule of methods of measurements and prices was decided upon, and this, with a number of rules and regulations governing the association, were published in book form for the guidance of painters and decorators throughout the whole United States. The work also gives many hints regarding various styles of work that are valuable and useful. The book, we believe, sells for two dollars to non-members of the association, and something less to members. The art of taking correct measurements is worth acquiring to the workman who does job work, for it is the little kinks in his work that make profit or loss, and he should be able to watch these kinks and turn them to his advantage.

The Plasterer's Measurements.

There has always existed more or less misunderstanding anent the "quantities" claimed by the plasterer, and where these quantities have been a subject of dispute it has always been found impossible for two measurements to agree; indeed, the plasterer himself cannot measure a building of any pretentions twice and get the same result each time. This may seem strange, but it is true, and, of course, there is a cause for it. In some localities the plasterer claims and gets full measure for all openings, in other places he gets half the openings, and in others, again, the openings are counted against him. Then again, the practice in some places is to give the plasterer the full height of a room, base and cornice included, while in others he is allowed the base but not the cornice, while yet in others he is allowed neither base or cornice. Again, it has never been decided what constitutes an opening. Some say an opening is just the space between the jambs of a door or window, while others claim that the opening is over all the wood trimmings, so if the casings were six inches wide, and the door three feet, then the opening would be four feet wide, the same with the windows. The following, however, which is taken from Vogdes, who is an authority on such matters, is generally considered fair and equitable all round. Plastering should be measured by the yard, nine square feet making one yard, and according to custom, no deductions is made for doors, windows and other openings which do not exceed sixty-three square feet. This is the custom that should obtain in Canada, in justice to the plasterer. In measuring closets another author says "it is customary to add half of the contents, and if the shelves and strips are in before plastering, double the contents. Small gables and other tri-angular pieces are counted square. These extra allowances are made to make up for extra labor of lathing and plastering such pieces of work." We can offer no objections to the measurements, as it is well known to workmen that it takes more time to lath and plaster these irregular places than if the walls offered straightforward work. With regard to the cornices and enriched work, Vogdes says "cornices that are plain running members are charged by the running foot, but enriched or carved mouldings are charged by the lineal foot. Paneled work, whether on walls or ceilings, run with a mould, should be rated by the foot superficial." In this case it seems the intention of Mr. Vogdes to charge as for plain work first, where the cornice is placed, and then for the cornice afterwards. This is probably just, as the plasterer has first to lath and then render the wall, before it is in condition to receive the cornice. For circular and elliptical work, two prices should be charged, and for domes or groined ceilings, three prices. He also states that for every twelve feet in height above the first floor, five per cent. should be obtained. These charges may look somewhat formidable on the face, but they are no more than long experience has proved to be just and fair between owner and contractor, and if they were universally adopted and adhered to, there would be less disputes between owners of buildings and their contractors.

Shingled Roofs.

A building that is not "well roofed" is in a serious stage of consumption, and should be placed under treatment at once. If the roof is one covered with shingles, and not old enough to have its timber in a state of decay, there will be but little trouble in making the roof as "tight as a drum," and free from leaks. There is no roof in existence that is so easily kept tight as a shingle

one. By "tight" we mean a roof that does not admit of water or of driven snow finding their way under them. It has become the custom of late years to lay a prepared paper or felt of some sort on the roof boards or sheeting, before the shingles are laid. This is done for a double purpose and is really a good thing to do. One of the purposes is because the paper assists in keeping the roof tight, making it warmer in winter and cooler in summer, another is because the paper or felt is said to be made incombustible and therefore, acts as a fire arrester, and when it can possibly be done, it is always in order to put a layer of some sort of unburnable fabric between the shingles and the sheeting. A shingle roof should always be painted with some oxide paint of suitable color, at least two coats. This painting is a good investment, as two coat work, when the shingles are laid will lengthen the life of the roof seventy-five per cent., and if this painting is followed up and the roof painted every five or six years, the life of it may be extended to almost any limit. Of course, something depends on the original quality of the shingles themselves. If they are made of good white pine, straight grained, the roof may be made to last a long time, and so, also, if the shingles are made of sound white cedar, but if cut from shakey or "dosey" stock, the life of the roof will be short, as they will rot from the underside. The cypress makes the king of shingles, so far as lasting qualities are concerned. There are many old buildings still standing in Southern New Jersey, Pennsylvania, Maryland and Delaware, that were covered with cypress shingles 150 and 175 years ago, that are still protected from the weather by the shingles that were first laid on, and they have not received a single coat of paint either, or any other composition. The life of an ordinary Canadian shingle is well within the limits of twenty-five years, if it is not protected by paint or other saving composition, owing, perhaps, to our rigorous climate and heavy rainstorms. An old roof, if not too far gone, may be greatly benefitted, if given a heavy coat of oxide paint and boiled linseed oil, but, after a roof has seen a half dozen winters or so, unpainted, it is a question whether it is an economy to paint it, as it will eat up an enormous amount of paint and oil to give it justice.

Mortar under Shingles.

Many architects insert a clause in their specifications calling for half an inch of rough mortar to be laid under the shingles. The object of this, of course, is to act as a non-conductor of heat and cold, and as a fire arrester. We have never been quite sure that the mortar has ever accomplished either of the purposes for which it was intended. The lime in the mortar certainly does no good to the shingles, but harm if rain ever gets to where the lime strikes them, and the shrinkage of the roof boards is sure to crack and break the mortar up, if it should escape being shattered by the hammering and pounding while the shingling is being done. The mortar used for the purpose is generally the most miserable stuff the plasterer can concoct, and the laying of it on the roof boards is not by any means done in the best style. On a flat roof it may be effective, but on a steep roof we have our doubts about it, and in the end we are constrained to think it is about as expensive as good roofing paper.

The stock of the Chanteloup Mfg. Co., Montreal, was damaged by fire a couple of weeks ago to the extent of $15,000.

LEGAL DECISIONS.

When Right to Lien is Waived. A mechanic's lien is waived or discharged where the parties enter into a special agreement inconsistent with the existence of the lien: as, for example, by the laborer or material man extending credit to the owner beyond the statutory period for bringing an action to enforce the lien. Flenniken v. Liscoe (Supreme Ct. Minn.), 66 N. Y. W. Rep., 979.

A motion for an injunction was made at Victoria, B.C., before the Chief Justice in Canessa v. Nicol to restrain the defendant from quarrying stone on plaintiff's property on Gabriola island. Plaintiff and defendant last year made an agreement whereby defendant for the sum of $25 was given the right to prospect on plaintiff's land, and for the sum of $300 a year could quarry sandstone there, with a further proviso that defendant had the option of purchasing the land at $10 an acre. Defendant decided to purchase, but plaintiff now alleges that when he signed the agreement he was not aware of the purchase clause in the agreement, and now wishes to eject defendant from the property. An affidavit on behalf of defendant stated that he is engaged in supplying stone from the quarry under contract for the new post office here. The court ordered that defendant be allowed to continue quarrying on payment into court of $300.

PERSONAL.

Mr. James T. Davis, of the firm of Davis & Sons, canal contractors, had one of his shoulders dislocated in a runaway accident recently.

Mr. Andrew Onderdonk, the millionaire contractor, who has lately resided in New York, will take up his residence at Hamilton, Ont. He has leased "Highfield," the Turner homestead, which Lord Aberdeen occupied while a resident of that city.

Mr. Willian McNichol, of St. Catharines, a contractor on the Hamilton Radial Electric Railway, was accidentally killed at Hamilton on the 23rd of June while crossing the Grand Trunk railway tracks, by being struck by a train. Deceased was fifty years of age, and leaves a wife and two children.

Quarter-sawed boards and bastard-sawed boards neither shrink nor wear alike, hence they should not be used side by side for best floors.

The Ontario Lead and Barb Wire Co., of Toronto, are said to have decided to establish a branch in Hamilton. They have secured the Dalby building on Hughson street for a factory, where they will manufacture plumbers' supplies, and barb wire and nails.

While the workmen were engaged in the construction of the Presbyterian church at Palmerston, Ont., one of the guy ropes slipped from its fastenings, and in an instant the whole of the heavy roof timbers crashed to the ground, killing a workman named John Whitely, about 35 years of age. Several others had very narrow escapes.

At the last regular monthly meeting of the Iron Founders' Association of Montreal, Mr. J. Best, of Messrs. Warden King & Son, who was their representative at the meeting of the National Association of Iron Founders, held recently in Philadelphia, and who was elected a Vice-President of that Association, gave a graphic and interesting account of the proceedings. The Montreal association will discuss the subjects at future meetings.

The annual excursion of the Toronto Builders' Exchange was held on Saturday, the 11th inst. The steamer "Tymon" carried over one hundred members of the Exchange and their friends to Wilson Park, N. Y., where an enjoyable day's outing was spent. The programme of sports was prepared mainly for the entertainment of the children, by whom they were thoroughly enjoyed. The weather was almost perfect and the sail across the lake was exceedingly pleasant. The excursionists returned to Toronto about 9 o'clock.

The bricklayers of Ottawa are endeavoring to arrange an eight hour day with the contractors. At present they are working nine hours per day, for which they receive three dollars. A proposition for a reduction has been before the bricklayers' union for some time and has lately been sent to a number of leading contractors. They ask 35 cents an hour for an average of eight hours a day during the week, arranged in such a way as to give a half holiday on Saturday. The contractors are believed to be adverse to the reduction on the above grounds, but are willing to pay wages at the rate of $3 for nine hours, or 33⅓ cents per hour.

MASTER PLUMBERS.

ORGANIZATION OF A DOMINION ASSOCIATION.

At the solicitation of the Master Plumbers' Association of Montreal, there convened in that city on the 2nd of July delegates from the different master plumbers' associations of the Dominion. The very desirable object for which the gathering was called together was the formation of a National Plumbers' Association for the Dominion, which would grapple with the many ques-

MR. JOS. LAMARCHE, President, Montreal.

tions of paramount importance to the trade, such as sanitary laws, plumbing licenses and examinations, etc. Letters were sent to each association requesting that a delegate be sent to represent their district, and the hearty response to the invitation indicated that the movement had met with approval.

There were present delegates from a number of the principal cities of the Dominion, as well as representatives from the National Association of the United States.

The representatives were as follows:

Toronto W. J. Burroughes, A. Fiddes, F. W. Armstrong.

Montreal—Joseph Lamarche, E. C. Mount, Alph. Champagne, J. W. Hughes, P. J. Carroll.

Kingston J. J. Jamieson, Robert Elliott.

London R. J. Haslett, Wm. Smith.

Quebec R. Sampson, O. Matte.

Ste. Hyacinthe A. Blondin.

Ottawa John McKinley.

Halifax George Perrior, John Borton.

St. John, N. B. J. H. Doody.

The delegates from the National Association of the United States were Messrs. J. F. Davlin, T. J. Tute and Isaac Riley.

In addition to the delegates there were present the following members of the Montreal association and representatives of supply houses:

S. Martin, Thos. Mott, John Foster, Wm. M. Briggs, C. A. Champagne, J. A. Marier, Jos. King, M. Germain, John Burns, Alf. Demers, John Watson, Lt. S. Stephenson, Fred. Horton, Geo. Henders, E. Lesperance, J. C. Jacotel, H. Baillie, Jas. Ballantyne, P. C. Ogilvie, Griffin Rosser, F. H. Barr, G. A. Berrier and Alf. Blais.

The chair was then taken by Mr. Joseph Lamarche, president of the local association, who addressed the delegates as follows:

GENTLEMEN:—In the name of the Master Plumbers' Association of Montreal, as Chairman, let me thank you most cordially for having accepted our invitation. I may state that we do not want to take all the honor upon ourselves of having convened this convention.

It is a long time since we desired to see the master plumbers united in one body, and we are very glad, therefore, that you come in such representative numbers from different parts of the Dominion. Let me thank especially those representatives who are here to represent the United States. It deserves special mention. They have had experience and are willing to show us the way to success, and let us benefit by their experience which they have derived from fourteen or fifteen years work. I really thank them most sincerely and welcome them to the City of Montreal.

There is another matter worthy of mention, namely, the Master Plumbers Journal, which is especially devoted to plumbing, etc. They have sent from New York Mr. Spiers, one of the staff, to represent their paper, and I thank them very much for the honor done us on this occasion.

There is no need of talking to you about the necessity of organization. We all know the good results to be obtained from it. The master plumbers of Montreal started an Association, as you know, some years ago, and did a great deal of work, but it did not turn out a success. A couple of years ago we united again, and we have done our best in Montreal to promote the success of organization, and I think the members of our Association deserve credit for having encouraged other places to help us in having this great convention to-day. At that time I believe there was only Toronto which had an organization. I do not think there was any organization in any other place in Canada, and to day we have representatives from ocean to ocean, from Toronto, Kingston, Ottawa, Montreal, St. Hyacinthe, Quebec, St. John, N. B., and Halifax, N. S. So gentlemen it says a good deal for the necessity of an organization.

It will not be out of place to mention a few reasons why we really need organization. Many people believe that we organize for the purpose of making dollars and cents. They must put away such an idea and we must make them understand we organize not for the reason they suppose, but in the interest of public health. There are many plumbers who do not know how to do their work, who do not understand the duties which appertain to their situation, or else they do not care to give themselves the trouble of executing them properly. I may say of Montreal, that a by-law was passed some time ago, prohibiting the use of tile pipe inside of buildings, but it was not enforced, and though the by-law was still in existence, bad work was

MR. W. J. BURROUGHES, Vice-President, Toronto.

allowed to be done. It therefore cannot be for dollars and cents that the master plumbers organized, since they can make more money by repairing tile pipes than by putting in iron ones. We organized, as I said before, in the interest of the public health.

Another reason is that a great many men go into this kind of work and know practically nothing about it, because they have served but a short apprenticeship; it is therefore the duty of this organization not only to look to the sanitary condition, but to see that proper workmen are turned out and fitted to do the work in the future. A third reason is that manufacturers and suppliers of all kinds are organizing to protect their own interests, and why should not we? We should not only organize in one particular city, but all through the country, all over the

Dominion, so that if necessary we can act in a body and maintain our rights.

As far as trade relations are concerned we have no other wish, but to live and let live. It is the only wish we have here, and I am certain there is no one who will refuse us the advantage of living as well as themselves.

Gentlemen let me thank you once more for having come here in such numbers, and let me express to you my heartiest feelings on the part of the Montreal Master Plumbers to have the honor of receiving you here for the first convention of the Dominion Master Plumbers of Canada.

Mr. Lamarche then made a short speech in French to those who did not understand English.

MR. J. W. HUGHES, Secretary, Montreal.

Mr. T. J. Tute, of Boston, was called upon to address the meeting. He said: I second Mr. Lamarche in saying that we have labored for fifteen years and have still work before us, not as a matter of making dollars and cents, but to protect the public. In building a school it is not so much the brick, the woodwork, and the painting that should be closely attended to, as the sanitary work. Where your children, my children, and children of the world are to meet it is most necessary that they have pure air to breathe, live and work in. When you go on board a steamer the first thing almost that one notices is a card hanging upon the wall indicating the qualifications of the engineer. It is just as important for our trade to have this same qualification. The world may call us the thieving, robbing plumbers; but, gentlemen, thieves and robbers grow rich, but you can find very few rich plumbers. We want to protect our own interests and to keep out impurity, and let innocence be uppermost, where God-like people may dwell in safety. And how are we to do it? It is by clasping hands with one another, with honorable, upright men throughout the world, to try and protect humanity from the cradle to the grave. We most heartily extend that protection to you to its utmost limit, and will always be pleased to do what we can to help you. We are all brothers of one family. You have my best and hearty sympathy and support.

Mr. F. J. Davlin, of Boston, followed, stating that it gave him much pleasure to extend to Canadian master plumbers the fraternal greetings of the master plumbers of the United States, and assure them of their hearty support at all times. Do not be backward, he said, in calling for aid, assistance or information that our association has in its power to give you.

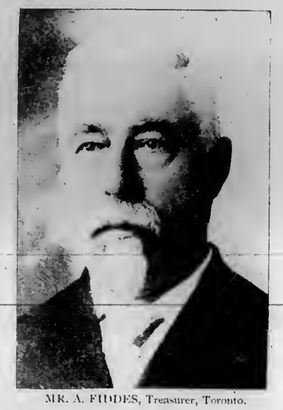
Mr. I. Riley, another delegate from the United States association, was then called upon, and expressed his pleasure at being present, and at seeing such a large number present.

The President stated that he had only taken the chair pro tem, but he was requested to continue in office, and Mr. J. W. Hughes, of Montreal, was appointed temporary secretary.

Messrs. R. F. Elliott, Kingston; F. W. Armstrong, Toronto, and O. Matte, Quebec, were then appointed a committee on credentials.

Mr. Burroughes, President of the Toronto Association, was asked to address the delegates. He related some interesting circumstances in connection with the plumbing business in Toronto, referring particularly to the strike of journeymen plumbers over the apprenticeship question in the year 1888, and which was finally won by the master plumbers, as the result of having an association, which had only been formed a year previous. With regard to association matters, he stated that he had always taken a great interest in them and done his best to further the interests of associations and to organize in adjacent cities. About a year ago he wrote the Montreal association about forming a national society, and it was decided that the Montreal association should look after the eastern provinces, and that Toronto would look after the west. Letters were sent to nearly every city in the Dominion, and in every instance a satisfactory reply was received. These steps had ultimately resulted in the meeting at which they were present. At London and Hamilton they had succeeded this year in forming associations. Adjoining these two cities were a number of towns, the plumbers of which would affiliate with the associations of London and Hamilton.

Mr. Borton, president of the Halifax association, said that as regards their association, it had only been organized about a year ago. At that time they saw that something must be done, as the jobbers down there



MR. A. FIDDES, Treasurer, Toronto.

were making a slaughter house of Halifax. A meeting was called, and after a little hard work the association was formed. There were three plumbers, he said, who did not belong to the association in Halifax, and who at the present time cannot get their goods in Canada, but they were getting them from the United States. This was causing the association some trouble.

Mr. Moody, of St. John, N. B., said that St. John was the first to move in the direction of forming an association in the maritime provinces, and Halifax followed. The latter branch, he admitted, had made

greater progress and had a larger membership than St. John.

The following were appointed as members of the committee on constitution and by-laws: Messrs. J. W. Hughes, Montreal; J. J. Jamieson, Kingston; W. J. Burroughes, Toronto; R. J. Haslett, London; R. Sampson, Quebec; A. Blondin, St. Hyacinthe; J. McKinley, Ottawa; J. Borton, Halifax; J. H. Doody, St. John, N. B., and R. F. Elliott, Kingston.

After a few words from Mr. R. F. Elliott, mayor of Kingston, the convention adjourned for lunch.

On reassembling, Mr. E. C. Mount was appointed sergeant-at-arms, and Mr. Hughes read the constitution and by-laws which the Legislative Committee had adopted, being those governing the National Association of Master Plumbers of the United States, with such amendments as were necessary to make the same conform to Canada. The by-laws were read clause by clause and adopted. They provided that the organization should be known as the National Association of Master Plumbers of the Dominion of Canada. It was organized for sanitary, commercial and social purposes, and had for its special objects the advancement appertaining to sanitary laws; to promote and combine the interests of the trade in the latest discoveries in sanitary science; the protection of the trade against imposition, injustice or encroachment upon their common rights or interests; encouraging inventions or improvements in sanitary appliances, fostering an interchange of thought, and eliciting and communicating for the benefit of each member the best talent and result of the experience and ability of all; to promote amicable relations with employees, on the basis of mutual interest and equitable justice to both journeymen and master plumbers; to encourage Dominion and Provincial legislation for the furtherance of the interest of sanitary laws; to secure for the members of the trade equitable treatment in their dealings with manufacturers and dealers in supplies; to regulate the system of apprenticeship and employment, so as to prevent, as far as practicable, the evils growing out of deficient training in the responsible duties of selecting, arranging, and fitting up materials relating to the hydraulic and sanitary condition of dwellings, public and private institutions; to create and maintain a sanitary code at as high a standard as the progress of science (chemical, philosophical and mechanical knowledge) teaches.

ELECTION OF OFFICERS.

Messrs. R. F. Elliott, Kingston, Alph. Champagne, Montreal, and W. Smith, London, were appointed a Nomination Committee, and reported in favor of the appointment of the following officers: President, Mr. Joseph Lamarche, Montreal; vice-president, Mr. W. J. Burroughes, Toronto; vice-presidents from each province represented, Messrs. William Smith, Ontario, O. Matte, Quebec, J. H. Doody, New Brunswick, and John Borton, Nova Scotia; financial and recording secretary, Mr. J. W. Hughes, Montreal; treasurer, Mr. Fiddes, Toronto; executive committee, to act in conjunction with the officers of the association, Ontario, R. F. Elliott, Quebec, E. C. Mount, New Brunswick, Thos. Campbell, Nova Scotia, Geo. A. Perior.

The report was unanimously adopted, after which the newly-elected officers returned thanks for the honor conferred upon them. Adjournment was then announced until 8 p. m., when the members met in secret session, at which the question of a protective policy was considered and the matter left in the hands of the executive committee.

SECOND DAY.

At 10 o'clock of the following day the convention resumed. In the absence of Mr. E. C. Mount, who was on the previous day appointed sergeant-at-arms, Mr. O. Matte, of Quebec, was appointed to act in his stead during the morning session.

At the request of the President, the delegates from the several associations reported the number of active members on the rolls as follows:—Halifax, 27; Montreal, 75; St. John, N. B., 12; Toronto, 35; London, Ont., 15; Ottawa, 9; Quebec, 37; Kingston, 7; Hamilton, 12; St. Catharines, 2; Toronto Junction, 1; Peterboro, 1; Galt, 2. St. Hyacinthe has no association, but a representative was present. The United States Association was stated to have a membership of 6,000.

The President reported that it had been decided to compose the Legislative Committee as under:—Messrs. J. McKinley, Ottawa, chairman; F. G. Johnson, Ottawa; A. Blondin, St. Hyacinthe; R. Sampson, Quebec; James Farquhar, Halifax.

The President announced that at 2 o'clock an official reception would be given by the mayor at the city hall, after which they would enjoy a drive through the city.

NEXT PLACE OF MEETING.

The selection of the place of meeting for the next convention was then taken up. Motions were offered in favor of Toronto, Kingston and Quebec. A vote was taken, with the result that Toronto was chosen as the meeting place for the second convention, the date to be fixed by the Executive Committee.

Mr. Hughes moved a vote of thanks to the National Association of Master Plumbers of the United States, which was acknowledged by Messrs. Davlin, Tute and Riley.

Mr. Elliott moved that the thanks be hereby tendered to the press for favors received, especially to Hardware and Metal, THE CANADIAN ARCHITECT AND BUILDER, and last, but not the least, to the Plumbers Trade Journal, and the able representatives sent here to assist us.

The President then called upon Lieut.-Col. Massey, of the Gurney-Massey Co., Montreal, to address the meeting.

Mr. Massey: I need scarcely assure you all that I did not expect you to call on me to say address you this morning. I should, however, fall very far short of my duty if I did not at once accede to your request. As a Montrealer in business here I can only assure those gentlemen from a distance who have come to assist you in forming a plumbers' association in the Dominion of Canada, that we are exceedingly glad to have you come to our city. I think the object of your association is very commendable. The duties of the Montreal association have been very carefully carried out heretofore. I have always loved to learn, and find that in going from place to place we can always derive a great benefit. I trust you may all have a very pleasant stay in Montreal.

Mr. Elliott moved, seconded by Mr. Burroughes, that the master plumbers of the Dominion desire to tender their sincere thanks to the Montreal Master Plumbers' Association for the hearty manner in which they have been received.

The motion was carried amid applause.

Votes of thanks were accorded to the president and secretary, which were suitably acknowledged.

The President then announced the adjournment of the convention.

SOCIAL FEATURES.

At 2 p. m. on the second day the delegates were received by His Worship, Mayor Wilson-Smith, at the city hall. A brief address of welcome was delivered by the Mayor, in which he stated that it was a matter for congratulation that so many business men of practical experience had gathered together to exchange ideas and aid the progress of a science which afforded protection, indirectly, to the commercial prosperity of the country. A visit was also made to the Council chamber, after which the delegates enjoyed a drive round the city by the courtesy of the Montreal members. At 5 p. m. the train was taken for Lachine, where a steamer was taken which carried them down the Lachine rapids.

In the evening the members celebrated the organization of a Dominion Association by a banquet at the Richelieu Hotel. About one hundred persons were present, and the chair was filled by the newly-elected president. The toast of the "Queen" was duly honored, and the health of "The Supply Houses" was responded to by Lieut.-Col. Massey, of the Gurney-Massey Co.; Mr. Sullivan, of Warden King & Son; Mr. McConochy, of Thomas Robertson & Co.; Mr. Glassford, of James Morrison, Toronto, and Mr. Anthes, of the Toronto Foundry Co. Other toasts were "The Visiting Delegates," "The Chairman," and "The Press," to which brief responses were made.

A strong effort is being made by the architects of the state of Washington to have congress make an appropriation to provide for the investigation and testing of American timber, with particular reference to Washington fir. The bill as now proposed, provides for an appropriation of $40,000 for the purpose, of which at least thirty per cent. shall be devoted to the testing of timber of the Pacific coast.

A class in bricklaying has been established in San Francisco, Cal., by a resident bricklayer who has been engaged in business for many years. The class is composed of boys from ten years of age upward, who take a lesson every day after school hours, and also on Saturday. An hour is spent in drawing to scale that which they build during the week. The pupils are the sons of the leading contractors of the city, and instruction is given in laying Roman, common and press brick, as well as how to do all kinds of work pertaining to the trade.

THE Gurney Foundry Company, Limited, of Toronto and Montreal, have recently opened large showrooms at 75 Finsbury Pavement, E.C., where they display a quantity of their hot water boilers and radiators (low pressure). After careful inspection their manufactures seem to be of the highest quality, both in materials and workmanship. This system of heating has given great satisfaction where it has been installed, and we may mention the following buildings in which this system may be seen in use:—The Tivoli Music Hall and Restaurant; the Union Bank, Princes Street, E.C.; the Garrick Theatre; Sir Charles Tupper's residence; Peek, Winch & Co., New Buildings, Eastcheap; London and Midland Bank, Peckham; and the New Fish Market, Farringdon Road, E.C.—British Architect.

ILLUSTRATIONS.

POST OFFICE, CUSTOMS, AND INLAND REVENUE OFFICES, VICTORIA, B. C.—THOS. FULLER, OTTAWA, ARCHITECT.

This building is being constructed on a plot of land bounded by Government, Courtney, Wharf and Humboldt streets. The outside walls are to be built of grey cretaceous sandstone from Gabriola Island, on a basement of granite, the partitions of the basement and ground floor to be brick, and the remaining partition, as well as the floors and roof, of wood, the roof covering to be of copper. There is to be a main portion, 136 ft. by 75 ft., having three full storeys, a basement and a mansard, and also an L-shaped annex of one storey and basement, having frontages of 107 feet and 103 feet on Courtney and Wharf streets respectively.

The main building is to be apportioned as follows: The basement to the heating apparatus, fuel, stores, water closets, etc.; the ground floor to the local post office; the first floor to the customs and finance; the second floor to the Inland Revenue and post office inspector's office, and the finished portion of the attic to the caretaker for a residence.

The annex will consist of a portion 75 feet by 26 feet, devoted to stores, a portion 109 ft. by 38 ft. for a bonded warehouse, and, in rear of the warehouse, a one-storey drive-way 30 ft. by 29 ft. The drive-way is 13 ft. wide, paved with granite, and leads from Humboldt street to the yard. Seven fire proof vaults are to be provided for the use of the several departments occupying the building. The building will be heated throughout by hot water direct heating.

Plans, specifications, and details for all the works, including fittings, heating, etc., were prepared by the Chief Architect of the Department of Public Works, Mr. Thos. Fuller, and the work is being carried out under the supervision of F. C. Gamble, departmental resident engineer at Victoria, B. C. The contractors for the construction of the building are Messrs. Elford Smith, Victoria, B. C., the fittings and heating not yet being contracted for.

CEMENT SIDEWALKS.

Repying to a correspondent who has had difficulty in making a cement sidewalk retain a smooth surface, a writer in Paving and Municipal Engineering says:—

"While the top mixture should be thoroughly rammed or beaten and well troweled, yet this treatment should not be continued so long as to bring to the surface a considerable quantity of neat cement, thus leaving the layer of mortar next below without sufficient cement to bind it together. If this is done, the thin layer of neat cement may flake off when set, revealing a layer of almost clear sand below. A similar result obtains if one attempts to retrowel a surface once finished and partially set but afterward defaced. Sprinkling the walk before the cement has thoroughly set may cause blisters which mar the appearance of the work; on the other hand, the walk should be protected from the direct rays of the hot sun, or surface cracks may result."

The following rules for the use of cement in freezing weather will be found useful:—As little water should be used as will permit a thorough incorporation of the materials. The water, sand, and stone may well be heated to about 100 degs. F., and in any case should be above 32 degs. F. Salt may be used in small quantities to delay freezing until the work is in place, or in larger quantities to prevent freezing until the cement has set and hardened sufficiently to resist the destructive tendency of the freezing weather.—Municipal Engineering.

CANADIAN ARCHITECT AND BUILDER.

VOL. IX.—No. 8. AUGUST, 1896 PRICE 20 CENTS $2.00 PER YEAR.

—THE—
CANADIAN ARCHITECT AND BUILDER,
A Monthly Journal of Modern Constructive Methods.
(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD).

PUBLISHED ON THE THIRD THURSDAY IN EACH MONTH IN THE INTEREST OF
ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

C. H. MORTIMER, Publisher,
Confederation Life Building, - TORONTO, CANADA.
Telephone 2362.
Branch Office: NEW YORK LIFE INSURANCE BUILDING, MONTREAL.
Bell Telephone 2299.

SUBSCRIPTIONS.

The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.

Prices for advertisements sent promptly on application. Orders for advertisemnets should reach the office of publication not later than the 12th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of technical value to the persons in whose interest this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publisher of any irregularity in delivery of paper.

Buildings for the Paris Exhibition.

FIFTY-NINE designs have been submitted in competition for the two principal buildings to be erected in connection with the Paris Exhibition of 1900. One of the buildings is to be devoted to the industrial and the other to the fine arts. The latter is to become the art gallery of the city upon the close of the Exhibition. The London Builder sums up a criticism of the leading designs by saying: "The competition is certainly not without interest, and represents an immense amount of work. But one can hardly say that it presents any great or epoch-making qualities of national architecture, though one must recognize that as the competitors have only had two months and a half in which to prepare their designs, the result under those circumstances is somewhat remarkable."

Free Silver Agitation.

THE possibility of the triumph of the advocates of free silver coinage at the approaching presidential election is seriously disturbing business conditions in the United States at the present moment. A clause requiring all payments to be made in gold coin, has become a common feature of business contracts, and the National Association of Builders have under consideration the advisability of embodying such a clause in the "Uniform Contract." Building operations in the large cities are, it is said, being seriously hampered by the refusal of financial institutions to make loans to builders and others, except under agreement for repayment in gold. The tremendous risk which a speculative builder would assume who should consent to such a stipulation is sufficient to deter most from proceeding with contemplated enterprises. The same uncertainty prevails to a greater or less extent throughout every department of business, and is exerting a paralyzing influence upon national enterprise.

The Province of Quebec Association of Architects.

THE Province of Quebec Association of Architects are to be congratulated on the progressive spirit in which they are endeavoring to promote the welfare and usefulness of the organization and advance the interests of architecture and the kindred arts in the Province of Quebec. During the present year meetings of the members resident in Montreal have been held monthly, at which interesting papers were read and discussed. Following these meetings the members have been accustomed to dine together and talk over in a social way

v.8-9
Canadian
archi

matters in which the Association is interested. No doubt as the result of this frequent intercourse and discussion, the Association has determined, with the assistance of the Arts Association of Montreal, to hold an Arts and Crafts Exhibition in the Art Galleries, commencing on the 8th of October, particulars of which are printed in our Montreal correspondence. It is to be hoped that the Ontario Association of Architects and other kindred societies will lend a helping hand to the enterprise. We doubt not the Exhibition will prove a gratifying success and a source of pleasure and instruction to all who may have the opportunity of visiting it.

Competitions.

It is very doubtful, indeed, if the conditions of architectural competitions in Canada are improving. They seem rather to be becoming more unsatisfactory as the years go by. For example, competitive plans were lately invited from architects throughout the Dominion and even in the United States for a public building to be erected in one of the remote parts of the country. When the designs were all in, and a meeting had been called to consider their merits, a member of the committee coolly suggested at the very outset that only the plans submitted by local architects should receive consideration. Fortunately there were on the committee men with clearer perceptions of equity, through whose influence the outside competitors received more considerate treatment. If it is the wish to give work of this character to local architects, the competition should be restricted to these. It is a most despicable proceeding to invite outside architects to submit designs, with the intention of appropriating the fruits of their study and skill for the benefit of a local architect. This, however, is the course which has been followed in more than one competition in this country.

The Good Roads Movement.

It is announced that in connection with the annual convention of the Ontario Good Roads Association to be held simultaneously with the Toronto Industrial Exhibition, there will be given an exhibition of road-making and road-making machinery. The movement for improving the public highways throughout Ontario was started at a most auspicious time, when the bicycle was commencing to achieve its prominence and popularity. The Good Roads Association can count upon the support of the army of bicyclists who have encountered the country road in all its deformity as it exists at present in many parts of the province. As large numbers of bicyclists are now to be found in every town and city in the Dominion, their advocacy should prove an important factor in bringing about the improvement which the Good Roads Association is endeavoring to promote. The appointment by the Ontario Government of Mr. Campbell, late city engineer of St. Thomas, as Provincial Road Instructor, has also been the means of giving strength to the movement. In this connection we notice that Mr. Campbell is not confining himself to giving instruction to the officials of rural municipalities, but is also placing his time and knowledge at the disposal of town and village corporations. In so doing it appears to us he is stepping beyond the legitimate bounds of his position, and is trenching upon work which the professional engineer might reasonably feel himself entitled to, and for which the municipality should feel called upon to pay.

The O. A. A. Conventions.

The Royal Institute of British Architects recently made a departure from their usual custom by holding their annual dinner in the town of Manchester. This action of the Institute has met with approval, its tendency being to encourage a closer intimacy between metropolitan and provincial architects, resulting in advantage to their mutual interests. We submit to the Council of the Ontario Association of Architects that if meetings of the Ontario Association were occasionally to be held in cities like Ottawa, Kingston, London and Hamilton, it might be the means of inducing the architects of those cities to take a deeper interest in the welfare of the Association and the objects which it aims to accomplish. The fact that a large proportion of the membership of the Association resides in Toronto is no reason why the meetings should always be held in that city, as the attendance of outside members is always proportionately as good as of city members. Seeing that many of the city members are so lacking in interest that they do not put in an appearance at the meetings, it is scarcely fair that the outside members should be called upon every year to bear the expense of coming to Toronto. The members have had ample opportunity to become acquainted with the architecture of Toronto. Would it not be advisable to introduce them to the architecture of the other cities of the province and afford the architects of those cities a chance of occasionally doing the honors?

Building Regulations in Toronto.

Immediately subsequent to the great fires which took place in Toronto in the early part of 1895, a committee of members of the Ontario Association of Architects spent much careful effort in the preparation of a building by-law for submission to the City Council. The Council at that time extracted from the proposed by-law a few clauses which were incorporated into the existing by-law. The remainder of the recommendations submitted have since received no attention at the hands of the aldermen, and from present appearance the disinterested labors of the committee will be to a large extent valueless. It is well known to those who have anything to do with building operations in Toronto that the existing by-law is full of imperfections, and furthermore that it is very loosely administered. We have frequently referred to the fact that perhaps in the majority of instances building permits are granted subsequent, instead of previous, to the commencement of the construction of the building; thus it becomes well nigh impossible to enforce compliance with the building regulations if these have been departed from by the designer or builder. The present by-law is noticeably defective in one or two particulars. Persons making application for a building permit are not required to submit with their plans a copy of the specifications, without which it is impossible to fully understand the manner in which the work is to be carried out. Again, no copy of the plans is kept on file in the building department, and there is consequently no means of knowing when changes are made in the original drawings. An instance of the laxity with which the by-law is administered came to light the other day when a scaffold which was being used in connection with some repairs to one of the departmental stores, gave way, resulting in injury to several workmen. On investigation it was found that the work was being carried out without a permit from the building department. It is desirable that the building by-law should be amended and properly administered, and during the present period of dullness, the City Council might profitably turn its attention to the matter.

Cheapening Production.

However much condemnation may be heaped upon "combines" of manufacturers in the same line of business for the purpose of maintaining prices at a point which would insure a fair margin of profit on invested labor and capital, much can be said in favor of such organizations. Overproduction in almost every line has resulted in competition which, if not restrained in some manner, must work disaster to manufacturers and their employees. To illustrate the effect which this striving after cheapness of production has upon the workman, we may cite the case of a manufacturer of a certain class of appliances used in building construction, who recently put in operation mechanical apparatus by means of which, with the assistance of a couple of laborers, he is enabled to do work which formerly required the services of eight skilled mechanics. This method of cheapening production has been forced upon him by the invasion of his territory by several new competitors. By and by these competitors will either be forced out of the field and suffer the loss of their capital, or will have discovered means of reducing the cost of production to a point which will enable them to hold their own in the race. When that time shall have arrived an effort must be made to further cheapen production, and so the struggle to outdo one another continued until the margin of profit is entirely wiped out, and the skilled workman reduced to the level of the laborer, with his chances of employment reduced in like proportion. Do the public want cheap goods at such a sacrifice? Whether they do or not, manufacturers should decline to sacrifice their interests and those of their employees to satisfy so unreasonable a demand. When competition reaches the point where there is no profit with which to pay a fair return to capital and labor, the combine becomes justifiable.

A Brightening Outlook.

It is gratifying to observe indications of a revival of building operations in Toronto, where a stagnation has prevailed for several years past. We are advised that owners of land in the out-lying districts are beginning to erect houses, owing to the fact that the extension of the street railway system, and the widespread use of the bicycle has made it possible for persons engaged in the business part of the city to reach the out-lying districts as conveniently, and in less time, than was required a few years ago to reach points a mile or two nearer the centre. The conditions of residence are certainly more desirable in the out-lying sections, and now that time and distance have to so large an extent been annihilated, it may reasonably be expected that comfortable houses in these districts will find tenants as readily as those in the more populous localities. The steady decline in the rate of interest is also inducing the erection of new buildings. Within the past few weeks, loans have been made on real estate in the city of Montreal at as low a rate as 4½ per cent., and we are informed that English capital is now available at this rate for any legitimate enterprise which gives promise of proving reasonably remunerative. With money available at this low rate of interest, persons who for a number of years have been holding vacant lands, from which they were unable to derive any revenue, and on which they were obliged to pay city taxes, are said to be coming to the conclusion that they might better build thereon a class of houses which would be likely to command a fair rental.

Taking a broader view, there are indications to be seen pointing to a more prosperous condition of affairs in Canada in the near future. The collapse of the South Africa boom, the unsatisfactory conditions prevailing in Australia, together with the unsettled state of affairs in the United States, as the result of which a large amount of British capital has recently been withdrawn from that country, and the possibility of the adoption of a silver coinage, which would lead to a still further withdrawal of British investments, all point to Canada as one of the most desirable fields for the investment of foreign capital in the future.

The recent gold mining developments in British Columbia are certain also to prove a most important factor in our future prosperity. We have the assurance of experts of the highest authority that the gold mines of British Columbia are the richest in the world. At the present time millions of foreign capital is being invested in these mines, and the prophesy is being made that a large influx of population will be received within the next few years. Owing to the disappointing experience of British capitalists who invested so largely in Grand Trunk securities, Canada has hitherto been shunned by the British investor, and other fields which were less promising have benefitted at our expense. It now seems probable that our turn will come in the near future. We have one of the richest countries in point of natural resources upon the face of the globe. We have also a favorable climate, and unrivalled transportation facilities. We lack capital and population, and it seems probable that these necessities are now about to come to us. If so, we may expect to witness improvement in every line, in which event no industry is likely to derive greater benefit than that in which architects, builders, and manufacturers and dealers in building materials are connected.

PERSONAL.

Mr. Anderson, Building Inspector, Hamilton, is recovering from a severe attack of typhoid fever.

Mr. Charles Rose, a well-known Toronto builder, died unexpectedly while visiting friends in Portsmouth, England.

Mr. R. P. LeMay, of the firm of Berlinguet & LeMay, architects, Quebec, is at present in Charlottetown, P. E. I., superintending the construction of the new Catholic cathedral in that city.

The appointment of Mr. E. G. Barrow to the position of city engineer of Hamilton, Ont., rendered vacant by the death of the late Mr. Haskins, has been officially announced. Mr. Barrow was assistant engineer for some time, and is thoroughly familiar with the details of the work. He was born at Clifton, near Bristol, Gloucestershire, England, forty-nine years ago, and educated in the Taunton College School. He served three years under Francis Fox, chief engineer of the Bristol & Exeter Railway of England, and at the expiration of that period his ability was recognized by his appointment as assistant engineer of the branches of the same road. Mr. Barrow came to Canada in 1871, and had charge of the work of locating the line of the Midland Railway, and afterwards that of the Northern & Northwestern from Georgetown to Collingwood. For the latter work the late Mr. Haskins was chief engineer. Thereafter Mr. Barrow worked for the city under Mr. Haskins, although not permanently appointed assistant until 1888. He superintended the construction of waterworks at Teeswater, Paisley and Campbellford, and also the Government waterworks at Mimico.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

ARTS AND CRAFTS EXHIBITION BY THE P. Q. A. A.

As briefly announced in the ARCHITECT AND BUILDER for July, the Province of Quebec Association of Architects will hold an Architectural and Arts and Crafts Exhibition in the Galleries of the Art Association, Phillips Square, commencing on Thursday, 8th October, 1896. This exhibition will consist of: (a) Architectural Drawings; (b) A Loan Collection of Antiques; (c) Modern Industrial Art in its Application to Architecture.

The Art Association of Montreal have kindly granted the use of their fine galleries for the purpose, and are co-operating with the Architects' Association in promoting the Exhibition.

Committees composed of members of the Association of Architects and Art Association have been appointed to select and arrange the exhibits. These Committees will have power to reject any work which in their opinion does not possess sufficient merit to entitle it to a place in the Exhibition.

The Architectural Section to consist of Pen and Ink and Colour Perspectives, Drawings of Original Designs, of Sketches in Ink or Colour of Old Work; all Drawings must be suitably framed.

The Industrial Art Section to consist of Stone and Wood Carvings and Sculpture, Original Architectural Models, Artistic Iron and Metal Work, Ornamental and Figure Glass Work and Original Cartoons for same, Original Designs for Wall Paper, Artistic Book Binding, Coloured Designs for Interior Decoration, Figure Mosaics in Glass, Marble or Tile, Architectural Ceramic Work, Textile Fabrics applicable to Interior Decorations, &c., &c.

As the space in the galleries is limited, articles for exhibition in the Industrial Section must be of reasonable size, and the Committee will exercise their discretion as to the size of articles that can be accepted.

Antiques loaned for exhibition will be sent for and returned to the owners, and will if required be insured on such terms as may be agreed upon.

Drawings and works other than Antiques are to be addressed to the Art Association, Phillips Square, and delivered there not later than the 24th September, and are to be removed immediately after the close of the exhibition, the delivery and removal to be at the risk and expense of the exhibitor.

Every care will be taken of the works while on exhibition, but no liability will be assumed for insurance, damage or loss from any cause whatever.

In connection with my reference last month to the forthcoming Loan Exhibit under the the direction of the P. Q. A. A., by a misprint the name "R. Findlay" appeared for that of Mr. R. Lindsay, of the Art Association, in the list of members of the Committee.

A DESIGN COMMITTEE.

The Committee of the Province of Quebec Association of Architects to consider designs submitted on different occasions is composed of the President, the Vice-Presidents and the Secretary. For this year the Committee is as follows: A. C. Hutchison, President; A. T. Taylor, 1st Vice-President; J. F. Peachy, 2nd Vice-President; Jos. Venne, Secretary.

STREETS OF MONTREAL.

The question of repairing the pavements on several of the streets is under consideration by the city fathers. Although it has been stated that the civic authorities intend to have the contractors make the repairs according to their agreement, nothing has yet been done. But it appears in many cases that the contractors' guarantee has expired, and the city will, in consequence, do the repairs at their own expense.

BY THE WAY.

THE payment by the city of Toronto of $15,000 to Mr. Mansergh, the English engineer, for a report on the best means of obtaining a sufficient and satisfactory water supply, was the subject of considerable comment a few months ago. It may interest our readers to learn that as engineer for the new water-works system of Manchester, England, Mr. Mansergh has received in commissions £102,000, or upwards of half a million dollars.

× × × ×

IN conversation with an architect the other day, I happened to touch on the subject of holidays, and was informed that Toronto Island was the farthest remove from the duties of his office that he had any expectation of reaching. Said he, "Did you ever think how peculiarly situated many architects are with regard to a vacation. If we are so fortunate as to have work on hand, we are obliged to stay at home and give it our attention, while if we haven't the work, we can't afford to take a holiday."

× × × ×

SOME enterprising plumber's apprentice has prompted the reporter of the Toronto World to suggest that master plumbers who wish to secure the largest share of the repair business should furnish their journeyman and helper with a tandem bicycle, thus effecting a saving of time in going to and from work, and a proportionate saving to the customer. There's nothing in it, either for the master plumber or his customer, but a great deal for the journeyman and apprentice, who, instead of being obliged to spend a few monotonous hours in the park, would have the opportunity of exploring the beauties of the various pleasure resorts adjacent to the city.

× × × ×

DURING the four or five years of business depression through which we have been passing, all classes have been on the lookout for indications of returning prosperity. As a rule they have seen little of an encouraging character, while with some things have been going from bad to worse. I met a man thus situated recently, to whom I propounded the oft-put question: "What is the business outlook?" The answer I received is worthy of preservation. Said he, "Two or three years ago you and I were living on our Faith that the times would improve. Last year we thought we could discern signs of promise and we lived on Hope. This year I am living on Charity."

CHIPS.

George Nelson, contractor, Rossland, B. C., was recently burned out.

The corner stone of the new Knox church at Woodstock, Ont., was laid a fortnight ago. The cost will be upwards of $45,000.

The Privy Council of England has confirmed the decision of the Supreme Court of Canada awarding Emanuel St. Louis, contractor, a balance of $63,642 on the Curran bridge, which the government had refused to pay.

The Pacific Coast Cement Company has been incorporated by J. C. Ferguson, C. W. Robson, H. J. Warsnap and T. R. Hardiman, of Vancouver. The object of the company is to acquire the Canadian Pacific Railway Company's cement works at Vancouver, and also the Saanich Lime Company's location on Tod Inlet, Saanich Arm. The capital is $500,000.

At the last meeting of master plumbers and steamfitters of Toronto, a communication was read from the City Council with reference to the lowering of the license fee. After a lengthy discussion it was resolved that a high license, and thorough examination, before allowing apprentices to work at the trade, were necessary to protect the master plumbers against unjust competition, and to insure good sanitary arrangements for citizens.

ILLUSTRATIONS.

DESIGN FOR A PRIVATE RESIDENCE, SUBMITTED IN THE FINAL EXAMINATION OF THE PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS, 1896, BY JOS. FORGET DESPATIE, MONTREAL.

DESIGN FOR CLUB HOUSE FOR ROYAL CANADIAN YACHT CLUB, TORONTO. DICK & WICKSON, ARCHITECTS.

This building was recently destroyed by fire. It was not an entirely new building, the original structure being a large square frame building, the towers and verandah being added to it, the shape and size making the improvements a rather difficult problem to deal with.

DESIGN FOR BROADVIEW AVE. CONGREGATIONAL CHURCH, TORONTO. DICK & WICKSON, ARCHITECTS.

The plan of this church is arranged with a slope in the floor towards the pulpit corner, and the choir was so placed that they could be both seen and heard without being obtrusibly near the preacher. The Sunday School room was to have been built with an auditorium several feet below the ground level. The roof is shown to have been constructed with three steel trusses over the entire span, the ceiling forming a shallow dome between them. The exterior was to have been of dark red brick and clear plaster in the timber work.

BRIDGE AT ISLAND PARK, TORONTO.

This bridge is an ornamental one of three arch spans, the centre one being 60 feet in the clear, and the two outer spans 30 feet in the clear; the roadway is 22 feet wide between parapets. The whole structure is of steel and cast iron, no woodwork being used except for bridge deck. The design for the bridge and all working drawings of the cast iron parapet, galvanized iron columns and other ornamental work were made at the office of the City Engineer, Toronto.

The masonry, piers and abutments were constructed by Mr. A. J. Brown, of Toronto, and the superstructure executed by the Central Bridge and Engineering Company, of Peterborough.

COMPETITIVE DESIGN FOR PROPOSED HIGH SCHOOL BUILDING, ST. JOHN, N. B.—CURRY, BAKER & CO., ARCHITECTS, TORONTO.

This design was submitted in competition in the ordinary way, that is to say, the School Board advertised for sketch plans for a twelve-room school, class rooms to be 28 ft. x 32 ft., 14 ft. high. Total cost not to exceed $45,000. No premiums were offered, but it was intimated that the design most approved would be adopted and the author appointed architect of the building. Before taking these steps the board sent a commission to Boston and other parts of the Eastern States to examine school buildings there, and an exhaustive report was returned, showing the buildings visited to be very costly for the amount of space provided.

The authors of this design proposed to heat and ventilate the building on the "blast fan" or "plenum" system, heat being provided from two steam boilers.

It was proposed to use buff pressed brick, with light green stone trimming, the roofs to be of red tile.

The Dominion Glass Company, of Montreal, has been incorporated, with a capital stock of $100,000.

Mr. W. H. Carrick, vice-president of the Gurney Foundry Co., Toronto, has returned from Great Britain, and appears to be well pleased with the prospects for the extension of the company's business in Europe.

THE LARGEST ARCHED ROOF RINK IN AMERICA.

DEY BROS., of Ottawa, are building the largest rink in America of the arch style, without posts. It is to be 246ft. long by 100ft. wide, and 58ft. 6in. high. The disadvantage of arched roofs is the settling of snow on the top. This is overcome by jack rafters, giving a pitch from 30 to 40 degrees.

To the front is built a two-storey structure. On the lower floor are two entrances into the parlors. Each parlor will be 22ft. x 42ft., and a long double-backed upholstered seat runs down the centre of each room. Above the main entrance is the Vice Regal box, sacred to the use of the Government party. On one side is a large banquet hall, and on the other three club-rooms. A gallery at front end and a promenade along the sides and rear afford accommodation for spectators.

The ice space will be 81x201 ft. The roof will be covered with 2,320 squares of shingles down to within 15 feet from the ground, from where it will be covered with iron sheeting.

OTTAWA LETTER.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

THERE are several buildings going up in this city, but not as many as last year. The Canada Atlantic coming into the heart of the city has necessitated the removal of some buildings, among them being Dey Bros.' rink. They are building another at corner Ann and Bay streets. The old military stores are used as a temporary station. It is the intention of the railway company to run the line right down to Brigham's ferry, at which place the bridge across to Hull is to be built.

The McLeod street Methodist church, on the corner of Bank street, is constructed of grey stone, and is to cost in the neighborhood of $30,000.

Grant's music hall, corner of Bank and Sparks streets, has been overhauled, the floor raised, and a gallery put in, under the superintendence of G. M. Bayley, architect.

The Contractors' Association of this city had at one time a prosperous association, but the meetings have been neglected and the rooms almost permanently closed.

Ottawa should have a master plumbers' association to keep up with the other cities of the province, but as there is no plumbing inspector, any person can call himself a plumber. We know of instances where ⅜-inch pipe has been used for service pipe.

The plumbers' supply houses seem to be busy. Law Bros. have large orders ahead. Thos. Lauson is recovering from the fire in which he lost many of his patterns, and F. G. Johnson & Co. have developed into a supply house.

The city authorities are helping the working man by the extensive improvements of the streets and sidewalks. As many as 250 men have been working on Sussex street day and night. $50,000 is being expended on granolithic sidewalks.

Wadsworth & McWhinney have opened up on Bank street under the name of the Ottawa Roofing and Cornice Works.

Douglas Bros. having withdrawn their branch from here, Mr. J. R. Douglas has formed a company under the name of J. R. Douglas & Co., to carry on business as roofers, heating engineers and cornice workers.

The Gas Company have recently completed a large building, containing 600,000 bricks. The building is 83 feet long and has a radius of 30 feet.

Orme & Sons' new block contains 800,000 bricks, is four storeys high, and faced with light colored pressed brick.

The Toronto Brass Company, Toronto, have commenced the manufacture of builders' hardware, gas and electric fixtures.

The Bras d'Or Marble Company, of West Bay, N. S., have recently received orders for the supply of large quantities of marble for building purposes. They are said to possess fourteen varieties of marble in the immense deposit at Marble Mountain, some of which are exceedingly beautiful. The company are taking steps to extend their trade, and as the bulk of granite used in Ontario and Quebec is imported from Italy, it is quite probable that a portion of this trade at least can be secured by Canadian companies.

TESTS OF PAVING BRICKS.

The accompanying table shows the results of tests of several kinds of paving bricks conducted under the direction of Mr. E. H. Keating, City Engineer of Toronto. The following particulars of the method of conducting the experiments are furnished in his annual report:

For the abrasion tests, the bricks, after being measured and weighed, are placed in a tumbler with 200 lbs. of foundry shot. The machine is then run for 2,000 revolutions at 30 revolutions to the minute. The bricks are then taken out and weighed, the percentage of loss estimated and returned to the tumbler, which is given another 2,000 revolutions at the same rate.

Upon the completion of the second 2,000 revolutions the percentage of loss from the original weight is again determined, and the loss in cubic inches for each square inch of surface can be calculated. The tumbler in use measures 24×37 inches, inside measurement. A good paving brick under this treatment should not lose more than 9 per cent. in 2,000 revolutions, and not more than 12.5 per cent. in 4,000 revolutions, nor should the loss in cubic inches per square inch of surface exceed 0.09.

The absorption test should be made with the whole brick and also with broken pieces after being thoroughly dried and allowed to cool. The length of time the bricks should be immersed is 3 days, during which time the brick must not absorb more than 2¼ per cent. of its weight. Most of this absorption appears to take place during the first day.

Size of Tumbler, 24 x 37 inches inside; 200 lbs. foundry shot; 30 revolutions per minute.

The biggest association of master painters in the world, considering the area of ground covered, is that of Pennsylvania. This consists of nearly fifty different local associations, in as many cities, towns and villages, so that practically every master painter in the state is a member. The association exists by no means to "put down" the working man; on the contrary, delegates from the journeymen's unions are invited to be present at some of the meetings, while great efforts are made in fostering technical education and the interests of the apprentices.

AN INTERESTING SUIT.

Koksilah Quarry Co. vs. the Queen, a case of much general interest and involving a large sum of money, was commenced before Mr. Justice Walkem at Victoria, B. C., recently. This was an action brought by the Koksilah Quarry Co. to recover $12,500 damages by reason of alleged breach of contract in connection with the supply of stone for the Provincial Parliament buildings. The petition recites that in 1893 the government approved of a quality of stone quarried by the company and asked them for tenders for the delivery of stone from their quarry, to be used in the erection of the said buildings, and the company accordingly sent in a tender. In reply the deputy commissioner wrote the company that their stone had been selected and urged them to proceed with all necessary quarry work so that there might be no delay when the stone was wanted.

Afterwards, in February, 1894, some stone was delivered at the site of the said buildings, and the company allege was accepted as a part performance of the contract and actually used, but about this time the contractor refused to accept any more stone, although suppliants were always ready and willing to go on and complete their part of the contract. The company further say that stone has been used and is still being used, which, under the terms of the agreement, could have been supplied by them.

The defence contended that they never contracted with the company for the stone, but that the contractor for the buildings, the late Frederick Adams, was the party who made the contract for the stone. It is further stated that the stone was condemned by the architect of the building as unfit for the purpose required.

A dispute has arisen between Mr. Borque, the contractor for the Dominion reformatory at Alexandria, Ont., and the government architect, regarding the foundation which is being laid, and the contractor has asked that an outside authority be called in. Mr. Perrault, of Montreal, has been asked by the Department of Public Works to report in the matter, and has consented.

CORRESPONDENCE.

[Letters are invited for this department on subjects relating to the building interests. To secure insertion, all communications must be accompanied by the name and address of the author, not necessarily for publication. The publisher will not assume responsibility for the opinions of correspondents.]

EFFECT OF THE CHICAGO CANAL ON CANADIAN WATER LEVELS.

To the Editor of the CANADIAN ARCHITECT AND BUILDER.

SIR:—Anent your query as to Mr. O'Hanley's remarks on the effect on our Canadian waters of the so-called Chicago Drainage Canal—but which has merely been called so to disarm suspicion, by conveying the impression of it's being a very trifling affair, while in reality intended as a maritime canal for commercial purposes, and which the Government at Ottawa must have been blind indeed to Canada's interests to have allowed to proceed without even a protest of any kind on the part of the Dominion—I have not seen anything of Mr. O'Hanley's report on the subject, but if, as I am told, this gentleman was, when too late, "appointed by the then Dominion Government to report upon the probable effect of the Chicago Drainage Canal upon the water levels in Canada," I fail to see why he should have limited his conclusions to Lakes Michigan and Huron, while it is evident that Lakes Erie and Ontario must be correspondingly affected, since these lakes are naturally made up not only of their own particular watersheds, but of the outflow of the upper lakes into them by the St. Clair and Niagara rivers; and while it is, moreover, doubly evident that the whole of the St. Lawrence river between Ontario and tide waters at Quebec or Three Rivers must be ten or a hundred fold more affected in its levels than are the great lakes, or in the ratio of the narrowness of the latter to the immense expanse of the former.

There is no doubt that every inch less in depth of water in the lakes must diminish by so much the draught to be given to every vessel frequenting these inland seas, to allow of their reaching to the same distances up rivers, into bays and creeks and other inland waters.

The effect of the drawing off of some 600,000 cubic feet of water from Lake Michigan has been variously stated at from one to seven inches, and this shallowing of the water has been correctly figured at millions of dollars loss on the combined lake trade.

But the difficulty and damage or loss, as far as the lakes are concerned, is not an irremediable factor, for it can be conjured and avoided by damming and locking the St. Clair and Niagara rivers and the outlets of Lake Ontario at Kingston, or preferably, and at less expense, below the Thousand Islands, and the waters thus raised again and kept up to any required level as in a reservoir; while, where the injury will admit of no remedy, and which does not appear to have as yet struck any one not even a professional engineer—notwithstanding that I was the very first in Canada or elsewhere to point out the evil and sound the note of warning as early as in January, 1895, (now more than 20 months ago) in an article then published in this journal, though written during the preceding December, 1894, and subsequently by letters to our Quebec papers, the Montreal Star of March 6, 1895, the Canadian Engineer, the New York Engineering Record, and my conclusions reproduced also by the Montreal Herald; I say, sir, that where the evil will not admit of any compensatory process, and must forever remain unremedied, is, or will be, when the "canal" is completed along the shores of the St. Lawrence between Kingston and tidal waters at Quebec or Three Rivers.

An inch of water less upon the lakes may be comparatively of no moment, and it is absolutely indifferent to lake traffic whether the lakes drain south towards the Gulf of Mexico or eastward to the Atlantic, towards the Mississippi or the St. Lawrence; but while the quantity of water illegally diverted from the St. Lawrence may be most trifling in its depth when minimized by being spread over such an area as that of our great lakes, not so, by any means, on the narrower waters of the rivers of which these lakes are feeders.

The flow of water over Niagara is hardly more than 18 million cubic feet per minute, so the quantity we are being robbed of by our "American Cousins" (600,000 cubic ft. per minute, as already stated), is not less than one-thirtieth, or 3⅓ per cent. of the whole, and without going into mathematical formulae to ferret out the exact number of inches by which the depth of flow must be effected, after allowing for the thereby slightly diminished velocity and slightly increased friction due to diminished depth, our people, unprofessional and all, will not be slow to see that, in the same way as in a sluice of any kind, a diminished quantity of water must be productive of less depth on the floor or bottom thereof, so must a diminished quantity of water flowing through the St. Lawrence, as of any other river, resolve itself into a lesser depth of water over the floor or bed of the river.

In Lake St. Peter, for instance, where the present depth of channel, as dredged out, at a cost of so many millions to the country, is still but 27½ feet or thereabout, and Montreal clamoring for the expenditure of another $5,000,000.00 to increase the depth to 30 feet, such depth, even if attained, would be reduced by some eleven inches, or say a foot in round numbers, the moment the Chicago canal were open; and then more millions would have to be thrown away in making up the deficit, while, so soon as deficit No. 1 were made up, the projected enlargement of the canal in question (and which is already provided for in the purchase of the right of way) would decrease the flow of the St. Lawrence by another 3½ per cent.; and the carrying off of the other projected ship canals from the great lakes towards New York and the Atlantic by way of the Hudson river successively another and still another and further or additional deficit of 5 and 10 per cent.; or a total of from 12 to 17 per cent., equivalent to a loss of depth and draught of one-eighth to one-sixth of the present flow through the St. Lawrence.

Nor would this decreased draught for all species of river craft affect the St. Lawrence only between Kingston and Quebec; but, though in a less degree, be prejudicial, retardatory of navigation far below Quebec, where, at the "Traverse," so-called, vessels would have to wait an additional hour for their full complement of water, both on their journey up and down, and thus lose two hours or more, which at present can be improved in loading or unloading, or in other useful ways.

Again, this dearth of water would in no way be confined to the St. Lawrence, but affect also its tributaries, as the Ottawa, the Richelieu, the St. Maurice and other feeders, where all river craft must henceforth forego the advantage of ascending these tributaries to anything like the wonted distance as of yore.

Sir, to me, the most outrageous feature of this whole concern is the daring and unfriendly spirit in which this work has been conceived, and by Congress sanctioned and proceeded with, in absolute disdain and mockery, so to say, of Canada and our people; for it cannot but strike everyone, as it struck myself the moment I read of it for the first time in December, 1894, and while glancing behind me at my map, that though Chicago be, it is true, some 500 miles within the northern frontier of United States territory, still are the waters of Michigan, as well as those of Superior, Huron, Erie and Ontario, and as much as these, the feeders of the St. Lawrence, and that, if anything, Canada has the best right to them, as they are mostly of northern watershed, and that the taking possession of any portion thereof, without agreement or without compensation to Canada, can therefore be looked upon solely as the grossest, the most outrageous spoilation of our national rights—a most pertinent lesson too—while our solons at Ottawa were during the interval fooling away their time in squabbling over the Manitoba school question, making it a subject of discord and disunion between us all, while the Pope of Rome is and has been long endeavoring to create peace and harmony between French and English, Protestants and Catholics, by his attempts at christian-like union and forbearance.

CHAS. BAILLAIRGE,
City and Civil Engineer.

Quebec, July 23, 1896.

CHIPS.

A piece of rapid construction has been that of the roadbed of the Moncton, N. B., street railway. The whole length of the main line is over 12,000 feet, or 2¼ miles. The work of construction occupied 47 days.

Charles Thompson, an employee of the Owen Sound Stone Company, was killed in the quarries at Orangeville on the 24th of July. He was standing on a coil of rope which was attached to a derrick, when the workmen on the derrick commenced to hoist it. Thompson endeavored to get off the rope and became entangled in it. He was carried up into the air and then fell with terrific force between two large rocks.

The privy council of England has dismissed the appeal from the judgment of the supreme court of Canada of December 9, 1895, affirming a decision of Mr. Justice Burbidge in the case of Ross and others against the Queen. The appellants brought an action in the court of exchequer of Canada by petition of right to recover from the Dominion government the sum of $231,806, which they claimed to be due on two contracts for the construction of sections 9 and 15 of the Intercolonial railway.

MANUFACTURES AND MATERIALS

ASBESTOS.

To the question, "What is asbestos?" it is not altogether easy to find an answer. Geologists classify it among the hornblends. In itself, asbestos is a physical paradox, a mineralogical vegetable, both fibrous and crystalline, elastic yet brittle, a floating stone, but as capable of being carded, spun and woven as flax, cotton or silk. It is apparently a connecting link between the vegetable and the mineral kingdom, possessing some of the characteristics of both. In appearance it is light, buoyant and feathery as thistledown; yet, in its crude state, it is dense and heavy as the solid rock in which it is found. Apparently as perishable as grass, it is yet older than any order of animal or vegetable life on earth. The dissolving influences of time seem to have no effect upon it. The action of unnumbered centuries, by which the hardest rocks known to geologists are worn away, has left no perceptible imprint on the asbestos found embedded in them. While much of its bulk is of the roughest and most gritty materials known, it is really as smooth to the touch as soap or oil. Seemingly as combustible as tow, the fiercest heat cannot consume it, and no known combination of acids will destructively affect the appearance and strength of its fibre, even after days of its action. It is, in fact, practically indestructible. Its incombustible nature renders it a complete protection from flames, but beyond this most valuable quality, its industrial value is greatly augmented by its non-conduction of heat and electricity, as well as by its important property of practical insolubility in acids.

Asbestos has been found in all quarters of the globe. It comes from Italy, China, Japan, Australia, Spain, Portugal, Hungary, Germany, Russia, The Cape, Central Africa, Canada (Fig. 1), Newfoundland, this country, and from Southern and Central America.

Notwithstanding this wide distribution of asbestos, the only varieties which at present appear to demand serious consideration, from a commercial point of view, are the Russian, the South African, the Italian and the Canadian.

Before the development of the Canadian fields, the Italian asbestos was supreme in the market. For nearly twenty years Italy has been looked to for the best grades of the fibre. From a point on the northern mountain slope of the Susa valley is taken the floss asbestos fibre, the appearance of which in gas stoves is so familiar. In the same locality is found a fine white powder of asbestos, which serves for paint and other purposes. The mining is carried on at a height of from 6,000 to 10,000 feet above sea level.

But the Italian asbestos industry, once so important, is already on the down grade. The difficulties of mining are very great, and unduly increase the cost of production. The asbestos itself, judged by the latest standards, is of inferior quality; it is not easy to spin, and it does not pulp well in the making of paper. The best grade is extremely rare, and its cost of mining and

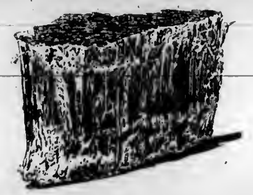

FIG. 1.—CANADIAN ASBESTOS.

transportation is prohibitive. The supply from the Italian mines is rapidly falling off. As a matter of fact, Canada contains the great asbestos region of the world, in the sense that while its mines are practically unlimited in productive capacity, the product is of a quality which fully meets the requirements of the newest and most exacting of the innumerable uses that are daily being found for it.

The process of manufacture is intensely interesting, more especially from the fact that as the industry is constantly entering upon novel phases, new methods of treatment and special machinery have to be devised. One of its special uses is for wall paper. This is a new application which will have a distinct effect in modifying the practice of indoor plastering. Instead of the ordinary tedious and elaborate preparation of studs and strips, and the use of inferior and dust creating mortar, with its after-scoring, which is necessary to give cohesion to the final coat of plaster of Paris, a single coating of the asbestos is laid on. It has a glossy surface that will not crack, as, while firm, it is perfectly flexible. It can be put on the raw brick; and a room of which the walls have been built in the morning can, before night, have a smoothly finished interior surface, shining like glass and as hard as a rock. A kindred application of asbestos is now coming into vogue in the shape of inflammable decorations for walls and ceilings. These are used a great deal for the saloons of steamships. They are embossed in very beautiful designs, and can be treated with gold, varnish, lacquers, or any other substance, for the enhancement of their ornamental effect.

Firemen clad in asbestos clothing and masks, as are those of London and Paris, can walk through the hottest flame with comparative impunity. Asbestos fireproof curtains have reduced the mortality of theatre fires in a very appreciable degree.

Probably one of the first applications of asbestos in this country

FIG. 2.—ASBESTOS MINING.

was to roofing. To buildings covered with this material, the shower of sparks from a neighboring conflagration involves no danger. The fact that woodwork can, by its use, be made uninflammable has come to be an important factor in the insurance of buildings.

One of the largest branches of asbestos manufacture is that of sectional cylinders for pipe coverings, for retaining the heat of steam and other pipes, felt protective coverings for boilers, frost-proof protections for gas or water pipes, and cement filling, which can be laid on with a trowel, for the covering of steam pipes, boilers or sills. In some of these cases, where it is only necessary to retain the heat, the asbestos is mixed with other substances; but where the protection must be fireproof as well, only asbestos is used.

Another very extensive department in asbestos manufacture is that of packings. Of these there are an infinite number of forms.

The making of asbestos paper varies from the building up of the thickest millboard to the production of a writing paper which, from its indestructibility, is valuable in case of fire for preserving charters, policies, agreements and other important documents.—George Heli Guy, in New York Evening Post.

Some twenty cars of stone, from the Tilsonburg quarries, have arrived at London for the construction of the Grand Trunk shops.

It is reported that Mr. Thomas Parker, proprietor of the Port Credit Pressed Brick & Terra Cotta Co., is negotiating for the purchase of the works of the Toronto Pressed Brick Company at Milton, Ont.

The French syndicate which recently purchased the St. John Stone Chinaware Co.'s potteries at St. Johns, Que., has completed its organization in Paris, and Messrs. Graves, Aube and Vannier, the promoters, sailed for Canada on the 15th inst. Mr. Adrian Vannier has been appointed manager.

CHARACTERISTICS AND PROPERTIES OF WOOD.

FROM a comprehensive discussion of the characteristics and properties of wood, prepared by Mr. B. E. Fernow, Chief of the Division of Forestry of the United States, the following valuable information for architects and engineers is obtained:

WEIGHT OF WOOD.

The two main factors of weight in wood are: The amount of cell wall, or wood substance, constant for any given piece, and the amount of water contained in the wood, variable even in the standing tree, and only in part eliminated in drying.

In general, it may be said that none of the native woods in common use in this country are, when dry, as heavy as water, i. e., 62 pounds to the cubic foot. Few exceed 50 pounds, while most of them fall below 40 pounds, and much of the pine and other coniferous wood weighs less than 30 pounds per cubic foot.

The weight of the wood is, in itself, an important quality. Weight assists in distinguishing maple from

WEIGHT OF KILN-DRIED WOOD OF DIFFERENT SPECIES.

	Specific weight.	Approximate. Weight of 1 cubic foot.	Approximate. Weight of 1,000 feet of lumber.
(a) Very heavy woods: Hickory, oak, persimmon, osage orange, black locust, hackberry, blue beech, best of elm, and ash	0.70-0.80	Pounds. 42-48	Pounds. 3,700
(b) Heavy woods: Ash, elm, cherry, birch, maple, beech, walnut, sour gum, coffee tree, honey locust, best of Southern pine, and tamarack	.60-.70	36-42	3,200
(c) Woods of medium weight: Southern pine, pitch pine, tamarack, Douglas spruce, western hemlock, sweet gum, soft maple, sycamore, sassafras, mulberry, light grades of birch and cherry	.50-.60	30-36	2,700
(d) Light woods: Norway and bull pine, red cedar, cypress, hemlock, the heavier spruce and fir, redwood, basswood, chestnut, butternut, tulip, catalpa, buckeye, heavier grades of poplar	.40-.50	24-30	2,200
(e) Very light woods: White pine, spruce, fir, white cedar, poplar	.30-.40	18-24	1,800

poplar. Lightness, coupled with great strength and stiffness, recommends wood for a thousand different uses. To a large extent weight predicates the strength of the wood, at least in the same species, so that a heavy piece of oak will exceed in strength a light piece of the same species, and in pine it appears probable that, weight for weight, the strength of the wood of various pines is nearly equal.

Since ordinary lumber contains knots and also more water than is here assumed, and also since its dimensions either exceed or fall short of perfect measurement, the figures in the table are only approximate.

Thus, 1,000 feet, B. M., of longleaf pine weighs:

	Pounds.
Rough and green	4,500
Boards, rough but seasoned	3,500
Boards, dressed and seasoned	3,000
Flooring, matched, dressed and seasoned	2,500
Weatherboarding beveled and dressed	1,500

The rapidity with which water is evaporated, that is, the rate of drying, depends on the size and shape of the piece and on the structure of the wood. An inch board dries more than four times as fast as a 4-inch plank and more than twenty times as fast as a 10-inch timber. White pine dries faster than oak. A very moist piece of pine or oak will, during one hour, lose more than four times as much water per square inch from the cross section, but only one-half as much from the tangential, as from the radial section.

In a long timber, where the end or cross sections form but a small part of the drying surface, this difference is not so evident. Nevertheless, the ends dry and shrink first, and being opposed in this shrinking by the more moist adjoining parts, they check, the cracks largely disappearing as seasoning progresses.

In thin boards all parts soon attain the same degree of dryness; in heavy timbers the interior remains moister for many months, and even years, than the exterior parts. Finally an equilibrium is reached, and then only the outer parts change with the weather.

With kiln-dried wood all parts are equally dry, and when exposed the moisture coming from the air must pass in through the outer parts, and thus the order is reversed. Ordinary timber requires months before it is at its best; kiln-dried timber, if properly handled, is prime at once.

Steaming the lumber is commonly resorted to in order to prevent checking and "case-hardening," but not, as has frequently been asserted, to enable the board to dry. Yard-dried lumber is not dry, and its moisture is too unevenly distributed to insure good behavior after manufacture. Careful piling of the lumber, both in the yard and kiln, is essential to good drying. Piling boards on edge or standing them on end is believed to hasten drying. This is true only because in either case the air can circulate more freely around them than when they are piled in the ordinary way. Boards on end dry unequally; the upper half dries much faster than the lower half, and horizontal piling is, therefore, preferable.

SHRINKAGE OF WOOD.

Shrinkage of wood is due to the fact that the cell walls grow thinner on drying. The thicker cell walls and therefore the heavier wood shrinks most, while the water in the cell cavities does not influence the volume of the wood. Owing to the great difference of cells in shape, size, and thickness of walls and still more in their arrangement, shrinkage is not uniform in any kind of wood. This irregularity produces strains, which grow with the difference between adjoining cells and are greatest at the pith rays. These strains cause warping and checking, but exist even where no outward signs are visible; they are greater if the wood is dried rapidly than if dried slowly, but can never be entirely avoided.

Temporary checks are caused by the more rapid drying of the outer parts of any stick; permanent checks are due to the greater shrinkage, tangentially, along the rings than that along the radius. This, too, is the cause of most of the ordinary phenomena of shrinkage, such as the difference in behavior of entire and quartered logs, "bastard" (tangent) and "rift" (radial) boards, etc., and explains many of the phenomena erroneously attributed to the influence of bark, or of the greater shrinkage of outer and inner parts of any log.

Rapidly dried in the kiln, the wood of oak and other hard woods "case-harden," that is, the outer part dries and shrinks before the interior has a chance to do the same, and thus forms a firm shell or case of shrunken, commonly checked wood around the interior. This shell does not prevent the interior from drying, but when this drying occurs, the interior is commonly checked along the medullary rays, as shown in fig. 1. In practice this occurrence can be prevented by steaming the lumber in the kiln, and still better by drying the wood

in the open air or in a shed before placing in the kiln. Since only the first shrinking is apt to check the wood, any kind of lumber which has once been air dried (three to six months for 1-inch stuff) may be subjected to kiln heat without any danger. Kept in a bent or warped condition during the first shrinking, the wood retains the shape to which it was bent and firmly opposes any attempt at subsequent straightening.

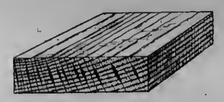

FIG. 1.—"Honeycombed" board. The checks or cracks form along the pith rays

To avoid "working," or warping and checking, all high-grade stock is carefully seasoned, preferably in a kiln, before manufacture. Thicker pieces may be made of several parts glued together; larger surfaces are made in panels or of smaller pieces covered with veneer. Boring is sometimes resorted to to prevent the checking of wooden columns.

Since repeated swelling increases the injuries due to seasoning, wood should be protected against moisture when once it is dry.

Since the shrinkage of our woods has never been carefully studied, and since wood, even from the same tree, varies within considerable limits, the figures given in the following table are to be regarded as mere approximations. The shrinkage along the radius and that along the tangent (parallel to the rings) are not stated separately in the following table, and the figures represent an average of the shrinkage in the two directions. Thus, if the shrinkage of soft pine is given at 3 inches per hundred, it means that the sum of radial and tangential shrinkage is about 6 inches, of which about 4 inches fall to the tangent and 2 inches to the radius, the ratio between these varying from 3 to 2, a ratio which practically prevails in most of our woods.

Since only an insignificant logitudinal shrinkage takes place (being commonly less than 0.1 inch per hundred), the change in volume during drying is about equal to the sum of the radial and tangential shrinkage, or twice the amount of linear shrinkage indicated in the table.

Thus, if the linear average shrinkage of soft pine is 3 inches per hundred, the shrinkage in volume is about 6 cubic inches for each 100 cubic inches of fresh wood.

APPROXIMATE SHRINKAGE OF A BOARD, OR SET OF BOARDS, 100 INCHES WIDE, DRYING IN THE OPEN AIR.

	Shrinkage.
	Inches.
(1) All light conifers (soft pine, spruce, cedar, cypress)	3
(2) Heavy conifers (hard pine, tamarack, yew), honey locust, box elder, wood of old oaks	4
(3) Ash, elm, walnut, poplar, maple, beech, sycamore, cherry black locust	5
(4) Basswood, birch, chestnut, horse chestnut, blue beech, young board	6
(5) Hickory, young oak, especially red oak	Up to 16

INFLUENCE OF WEIGHT AND MOISTURE ON STRENGTH.

It has been stated that heavy wood is stronger than lighter wood of the same kind, and that seasoning increases all forms of resistance. Let us examine why this is so.

Since the weight of dry wood depends on the number of fibers and the thickness of their walls, there must be more fibers per square inch of cross section in the heavy than in the light piece of the same kind,* and it is but natural that the greater number of fibers should also offer greater resistance, i. e., have the greater strength.

The beneficial influence of drying and consequent shrinking is two-fold: (1) In dry wood a greater number of fibers occur per square inch, and (2) the wood substance itself, i. e., the cell walls, become firmer. A piece of green longleaf pine, 1 by 1 inch and 2 inches long, is only about 0.94 by 0.96 inch and 2 inches long when dry; its cross section is 10 per cent. smaller than before, but it still contains the same number of fibers. A dry piece 1 by 1 inch, therefore, contains 10 per cent. more fibers than a green piece of the same size, and it is but fair to suppose that its resistance or strength is also about 10 per cent. greater.

The influence of the second factor, though unquestionably the more important one, is less readily measured. In 100 cubic inches of wood substance the material of the cell walls takes up about 50 cubic inches of water and thereby swells up, becoming about 150 cubic inches in volume. In keeping with this swelling the substance becomes softer and less resistant. In pine wood this dimunition of resistance, according to experiments, seems to be about 50 per cent., and the strength of the substance, therefore, is inversely as the degree of saturation or solution.

SOME PRACTICAL CONCLUSIONS.

In framing, where light and stiff timber is wanted, the conifers excel; where heavy but steady loads are to be supported, the heavier conifers, hard pine, spruce, Douglas spruce, etc., answer as well as hardwoods, which are costlier and heavier for the same amount of stiffness. On the other hand, if small dimensions must be used, and especially if moving loads are to be sustained, hardwoods are safest, and in all cases where the load is applied in form of "shocks" or jars, only the tougher hardwoods should be employed. The heavier wood surpasses the lighter of the same species in all kinds of strength, so that the weight of dry wood and the structural features indicative of weight may be used as safe signs in selecting timber for strength.

In shaping wood it is better, though more wasteful, to split than to saw, because it insures straight grain and enables a more perfect seasoning.

For sawed stock the method of "rift" or "quarter" sawing, which has so rapidly gained favor during the last decade, deserves every encouragement. It permits of better selection and of more advantageous disposition of the wood; rift-sawed lumber is stronger, wears better, seasons well, and is less subject to warping.

All hardwood material which checks or warps badly during seasoning should be reduced to the smallest practicable size before drying, to avoid the injuries involved in this process; and wood once seasoned should never again be exposed to the weather, since all injuries due to seasoning are thereby aggravated. Seasoning increases the strength of wood in every respect, and it is therefore of great importance to protect wooden structures, bearing heavy weights, against moisture.

Knots, like crossgrain and other defects, reduce the strength of timber. Where choice exists, the knotty side of the joist should be placed uppermost, i. e., should be used in compression.

Season checks in timber are always a source of weakness; they are more injurious on the vertical than on the horizontal faces of a stringer or joist, and their effect continues even when they have closed up, as many do, and are no longer visible.

DURABILITY AND DECAY.

All wood is equally durable under certain conditions. Kept dry or submerged, it lasts indefinitely. Pieces of

* This imperfect assumption is used only for comparison.

pine have been unearthed in Illinois which have lain buried 60 or more feet deep for many centuries. Deposits of sound logs of oak, buried for unknown ages, have been unearthed in Bavaria; parts of the piles of the lake dwellers, driven more than two thousand years ago, are still intact.

FIG. 2.—"Shelf" fungus on the stem of a pine. (Hartig.) a, sound wood; b, resinous "light" wood; c, partly decayed wood or punk; d, layer of living spore tubes; e, old filled up spore tubes; f, fluted upper surface of the fruiting body of the fungus, which gets its food through a great number of fine threads (the mycelium), its vegetative tissue penetrating the wood and causing its decay.

On the radial section of a piece of pine timber, with one of the shelf-like fungus growths, as shown in fig. 2, both bark and wood are seen to be affected. A small particle of the half-decayed wood presents pictures like that of fig. 3. Slender, branching threads are seen to attach themselves closely to the walls of the cells, and to pierce these in all directions. Thus these little threads of fungus mycelium soon form a perfect network in the wood, and as they increase in number they dissolve the walls, and convert the wood substance and cell contents into sugar-like food for their own consumption. In some cases it is the woody cell wall alone that is attacked. In other cases they confine themselves to eating up the starch found in the cells, and merely leave a stain (bluing of lumber). In all cases of decay we find the vegetative bodies, these slender threads of fungi, responsible for the mischief. These fine threads are the vegetative body of the fungus, the little shelf is its fruiting body, on which it produces myriads of little spores (the seeds of fungi). Some fungi attack only conifers, others hardwoods; many are confined to one species of tree, and perhaps no one attacks all kinds of wood. One kind produces "red rot," others "bluing." In one case the decayed tracts are tubular, and in the direction of the fibers the wood is "peggy." In other cases no particular shapes are discernible.

FIG. 3.—Fungus threads in pine wood. (Hartig.) a, cell wall of the wood fibers; b, bordered pits of these fibers; c, thread of mycelium of the fungus; d, holes in the cell walls made by the fungus threads, which gradually dissolve the walls as shown at e, and thus break down the wood structure.

It appears that warmth, preferably between 60° and 100° F., combined with abundance of moisture (but not immersion), is the most important condition favoring decay, and that the defence lies in the proper regulation or avoidance of these conditions, or else in the use of poisonous salts, which prevent the propagation of fungi.

STIFFNESS.

If 100 pounds placed in the middle of a stick 2 by 2 inches and 4 feet long, supported at both ends, bend or "deflect" this stick one eighth of an inch (in the middle), then 200 pounds will bend it about one-fourth inch, 300 pounds three-eighths inch, the deflection varying directly as the load. Soon, however, a point is reached where an additional 100 pounds adds more than one eighth inch to the deflection—the limit of elasticity has been reached. Taking another piece from the straight grained and perfectly clear plank of the same depth and width, but 8 feet long, the load of 100 pounds will cause it to bend one eighth inch, but will deflect it by about 1 inch. Doubling the length reduces the stiffness eightfold. Stiffness then decreases as the cube of the length.

Cutting out a piece 2 by 4 and 4 feet long, placing it flatwise, so that it is double the width of the former stick and loading it with 100 pounds, we find it bending only one-sixteenth inch; doubling the width doubles the stiffness.

Setting the same 2 by 4 inch piece on edge, so that it is 2 inches wide and 4 inches deep, the load of 100 pounds bends it only about one sixty-fourth inch; doubling the thickness increases the stiffness about eightfold.

It follows that if we double the length and wish to retain the same stiffness we must also double the thickness of the piece.

A piece of wood is usually stiffer with the annual rings set vertically than if the rings are placed horizontally to the load.

Cross grained and knotty wood, to be sure, is not as stiff as clear lumber; a knot on the upper side of a joist, which must resist in compression, is, however, not so detrimental as a knot on the lower side, where it is tried in tension.

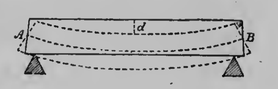

FIG. 4.—BENDING A BEAM.

Every large timber which comes from the central part of the tree contains knots, and much of its wood is cut more or less obliquely across the grain, both conditions rendering such material comparatively less stiff than small clear pieces.

The same stick of pine, green or wet, is only about two-thirds as stiff as when dry. A heavy piece of long leaf pine is stiffer than a light piece; heavy pine in general is stiffer than light pine, but a piece of hickory, although heavier than the pine, may not be as stiff as the piece of longleaf pine, and a good piece of larch exceeds in stiffness any oak of the same weight.

Since it is desirable, and for many purposes essential, to know beforehand that a given piece with a given load will bend only a given amount, the stiffness of wood is usually stated in a uniform manner and under the term "modulus (measure) of elasticity."

If AB, fig. 4, is a piece of wood, and d the deflection produced by a weight or load, the elasticity of the wood, as usually stated, is found the formula:

$$\text{Modulus of elasticity} = \frac{W\,l^3}{4\,D\,b\,d^3}$$

where W is the weight, l the length, b and d the breadth and depth of the stick, and D the deflection for the load W. In the following table the woods are grouped according to their stiffness. The figures are only rough approximations which are based on the data given in Vol. IX of the Tenth Census. The first column contains the above modulus, the second shows how many pounds will produce a deflection of 1 inch in a stick 1 by 1 by 12 inches, assuming that it could endure such bending within the limits of elasticity, and the third column gives the number of pounds which will bend a stick 2 by 3 inches and 10 feet long through 1 inch.

The stick is assumed to rest on both ends; if it is a

cantilever, i.e., fastened at one end and loaded at the other, it bears but half as much load at its end for the same deflection.

From the third column it is easy to find how many pounds would bend a piece of the same kind of other dimensions. A 2 by 4 inch bears eight, a 2 by 6 inch twenty-seven times as much as the 2 by 2 inch; a piece eight feet long is about twice as stiff as a 10 foot piece; a piece 12 feet, only about three-fifths, 14 feet one-third, 16 feet two-ninths, 18 feet one-sixth, and 20 feet one-eighth as stiff.

The number of pounds which will bend any piece of sawed timber by 1 inch may be found by using the formula:

$$\text{Necessary weight} = \frac{4\ E\ bd^3}{l^3}$$

where E is the figure in the first column, b, d, l, breadth, depth and length of the timber in inches. If the deflection is not to exceed one-half inch, only one-half the load, and if one-fourth inch, only one-fourth the load is permissible.

To allow for normal irregularities in the structure of wood itself, as well as in the aggregate structure of timbers, an allowance is made on the numbers which have been found by experiment; this allowance is called the "factor of safety." Where the selection of the wood is not very perfect, the load is a variable one, and the safety of human life depends on the structure; the factor is usually taken quite high, as much as 6 or 10, i. e., only one-sixth or one-tenth of the figures given in the tables is considered safe, and the beam is made six to ten times as heavy as the calculation requires

THE VALUE OF ADVERTISING.

ONE of the largest advertisers in London says: "We once hit upon a novel expedient for ascertaining over what area our advertisements were read. We published a couple of half-column ads, in which we purposely misstated half a dozen historical facts. In less than a week we received between 300 and 400 letters from all parts of the country, from people wishing to know why on earth we kept such a consummate idiot, who knew so little about English history. The letters kept pouring in for three or four weeks. It was one of the best paying ads. we ever printed, but we did not repeat our experiment, because the one I refer to served its purpose. Our letters came from school-boys, girls, professors, clergymen, school-teachers and, in two instances, from eminent men who have a world-wide reputation. I was more impressed with the value of advertising from those two advertisements than I should have been by volumes of theories." Exchange.

Large quantities of asbestos are now being shipped from the Thedford mine in Quebec to England.

Allister McKay, contractor, Chatham, has succeeded in perfecting a mammoth steam plow, which is now in successful operation on his Point Pelee farm. The plow is propelled by a steam engine at each end of the field, and performs its work fast and effectively.

STUDENTS' DEPARTMENT.

AN IRISH COMPETITION.

THE corporation of Belfast, Ireland, invite sketch designs for a new city hall, to cost £150,000. Mr. Alfred Waterhouse, R. A., and Mr. Bretland, City Surveyor, are the assessors. The authors of the three selected designs will be required to engage in a final competition, and among these the sum of £300 will be equally divided. The City Surveyor will furnish a copy of the conditions on payment of one guinea. The competition will close on the 25th of October.

"CANADIAN ARCHITECT AND BUILDER" STUDENTS' AND DRAUGHTMEN'S COMPETITION.

THE reports of the committees, composed of members of the Province of Quebec Association of Architects and of the Ontario Association of Architects, who kindly undertook to judge the merits of the designs submitted in the above competition, have been received, and are printed in full as follows:

"The Committee of the Province of Quebec Association of Architects appointed to consider the designs submitted in the CANADIAN ARCHITECT AND BUILDER competition for a frontispiece for the New Year Number, 1897, herewith beg to present their report.

Seven designs were submitted. Of these the one sent in under the motto of "Dix" we ruled out of the competition, for the reason that it is an exact copy of a drawing published in the American Architect of October 22, 1892, by W. M. Maccafferty, being one of a series of sketches made by him as American Architect Travelling Scholar, 1892.

"Ich Dien" we were also compelled to rule out of the competition as not complying with the published conditions as to size.

"Wilmot" we also ruled out as being in pencil and not complying with the conditions as to size.

Of the others we consider that none are of sufficient merit to be awarded a prize, nor do we consider them suitable for the object sought.

ALEX. C. HUTCHISON, President.
ANDREW T. TAYLOR, Vice-President.
JOS. VENNE, Secretary.

TORONTO, Aug. 3rd, 1896.

The problem to be solved by this competition, viz: "a front cover for the New Year Number of the CANADIAN ARCHITECT AND BUILDER, was by no means an easy one, and in the committee's opinion it is not surprising that the result should not be satisfactory. The subject is outside the ordinary scope of architecture. It called for a superior quality of draughtsmanship, and most of all for considerable designing ability, and therefore rather beyond the capabilities of the average student. Moreover, the problem was not merely to design an ordinary journal frontispiece, but one that should be distinctively architectural and which should present the ideal rather than the practical side of architecture. For example, if the design was intended to depict some notable architectural monument either in whole or in part such representation should either be conventionalized or it should form a portion only of the whole composition, being supplemented by something more idealistic. At the same time simplicity of design is of first importance, and a crowded or complex composition is to be avoided. This defect is forcibly illustrated in the design submitted by "Wilmot." Here both the real and the ideal are presented (and for this it is to be commended,) but so many insignificant and feeble details are introduced as to completely mar the whole effect. On the other hand the design by "Dix," who selects an entrance doorway, is lacking in ideal qualities, it being solely a representation of an old doorway in Siena, Italy.

The committee, after an examination of the various designs, would award the first place to "Ich Dien" and the second to "Confident."

The design under motto of "Dix," before referred to, while being an excellent example of artistic draughtsmanship, and under proper conditions worthy of a high place, we must decline to consider, as it is an exact copy even to the most minute detail (the original draughtsman's initials only excepted) of a drawing by Mr. W. M. Maccafferty, as published in the American Architect of October 22nd, 1892.

As to the other designs the committee would make the following comments and criticisms:

"Ich Dien" easily occupies the first place. The subject chosen is a domestic doorway in the Renaissance style, the steps with side parapets of stone surmounted by ornamental lamp standards in wrot iron or other metal. The composition is quite artistic, it is well drawn and the lettering is good and well arranged. Its chief fault is a certain smallness and prettiness suggestive of the decorative accessories of architecture rather than of architecture itself.

"Confident" submits a well drawn design in many respects, suitable and appropriate. It is, however, devoid of artistic feeling and very commonplace in design. The brackets under the cornice and the outline of the parapet or pediment over cornice are particularly objectionable. The figures and the Ionic capital in the pediment are good.

"Lion" sends a carefully drawn design, devoid of architectural character. It would be quite as appropriate for a journal devoted to the interests of agriculture.

"Wilmot's" design has already been criticised. It, moreover, has the disadvantage of being in pencil only.

In the case of "Le chat noir" the criticism applied to "Lion" would be equally applicable, with the further defect of extreme paucity of ideas.

"Heman's" design is commonplace and badly proportioned, while the drawing of the ornamental or freehand portions is very indifferently rendered.

GRANT HELLIWELL,
F. S. BAKER,
J. FRANCIS BROWN,
Committee.

In view of the fact that none of the designs submitted possess standard of merit which would justify their use for the purpose intended, we regret to be obliged to withhold the awards, as in the conditions we reserved our right to do. As we feared at the outset, the subject of the competition proved to be somewhat unfamiliar to and beyond the scope of the students and draughtsmen in a young country such as Canada, but we are pleased that so many were to be found willing to make the attempt to meet the requirements. We exceedingly regret that one of the competitors a clever draughtsman should have had so little ambition and such small sense of honor as to attempt to palm off upon the judges as the product of his own brain an exact copy of a formerly published illustration of a well-known existing piece of architecture.

A CHAPTER FROM THE BOOK OF COMPETITIONS.

PERHAPS the following amusing skit may enable those interested to fully realize the difficulties of a competition, and the very natural dissatisfaction of competitors with awkward conditions which are not after all taken as binding conditions in settlement:

2. In the beginning was a certain place, named Seadrain, and great was the dirt around it.

2. And certain of the people shouted, saying, "We would wash, but baths there are none."

3. And others that were in it said, "We would read, but books there are none."

4. Then those in authority spake unto the people saying, "Will ye be rated therefor?"

5. And the people shouted "Yea," and the law went out.

6. And the head men of the parish wrote to Cautious street, where is the Society for the Protection of Young Ideas and Gray Hairs, saying,

7. "Name, we pray thee, an adviser, one of exceeding good judgment and cunning, that we walk in the paths of Wisdom."

8. And the wise man named one of exceeding great respectability, whose works none knew nor could cavil at.

9. And the accessor shut him in a secret place, and communed with his own spirit, and the understanding which was in him.

10. But he walked not in the ways of Damp-cottage, whose wisdom is always most evident.

11. For the papers he drew up contained those things which they ought not to have contained, and left unsaid many things that ought to have been said, and there were many words and little common sense in them.

12. And they laid burdens grevious and impossible to carry out on the backs of the competitors, while the assessor smiled to himself, saying,

13. "Many printed pages have I written that the Building Committee may laud and magnify me for all time."

14. "For they will say, careful is he and of exceeding cunning; these fellows of architects we have chastised with whips, but he breaketh their backs with scorpions."

15. Then certain of the profession murmured and raised an outcry, saying,

16. "Hard and impossible are our conditions; how can a market be a town hall, or a fish be a serpent in aspect?"

17. "And why should we of the profession make details useless and unnecessary to thy judgment?"

18. "How can we judge of old lights, knowing not what existed of old time?"

19. But the assessor hardened his heart and laughed in his sleeve, saying,

20. "It is practice most excellent for ye, and in no way will I save ye the trouble."

21. And he finally gave judgment in this wise, pronouncing,

22. "Rabbit place 1 first, and others second and third in merit."

23. And certain of the competitors muttered and murmured aloud, saying,

24. "Thou regardest not thy own conditions, nor givest judgment by thy printed provisions."

25. But he was exceeding merry and laughed again, and told them,

26. "No man hath kept the conditions to the letter, for the conditions were impossible and in many ways utterly needless."

27. "Lo, I could have thrown all ye aside, saying,

28. "Fools and idiots were ye, not to see you were trapped, and but sheep for the slaughter."

29. "No one will believe ye or listen to your cries, but will only speak thus and thus,

30. "He envieth one Rabbit, and his soul is utterly filled up with blackness."

31. Thus it took place that men might write in after time, saying,

32. Easier is it for a camel to gallop through the eye of a needle, than for justice and wisdom to be evident in the conduct of a competition. W. W. H., in the British Architect.

In filling up a cracked ceiling, use a plaster putty to which some glue size has been added, but take care to cut out the cracks in a V shape so as to form a key.

To make a tint stand well we must have at least two good coats of the same colour, on a good, firm, even foundation; and it is better still if the prime coat is tinted with the same colour.

STRENGTH OF STEEL. An experiment with a view to ascertain the relative resistance, under pressure, of the hardest steel and the hardest stone, was recently made at Vienna. Small cubes, measuring 1 centimeter of corundum and of the finest steel, were subjected to the test. The corundum broke under the weight of six tons, but the steel resisted up to forty-two tons. The steel split up with a noise like the report of a gun, breaking into a powder, and sending sparks in every direction, which bored their way into the machine like shot.

THE BUILDER

The National Association of Builders.

The tenth annual convention of the National Association of Builders of the United States will open at Buffalo on September 15th. In view of the recent change of methods on the part of the labor unions in substituting for strikes a united effort to wrest from the governing bodies such legislation as will secure to them advantages over the employers, the National Association propose at their approaching convention to discuss thoroughly the reasons for and against the Association of Builders. It is felt that if the master builders are not to be placed at the mercy of the unions they must seek by as perfect organization as possible to protect their rights and interests. Some of our Canadian master builders might profitably attend the Buffalo convention, get thoroughly imbued with the ideas of their American contreres, and on their return to Canada set the ball rolling in favor of a Provincial or Dominion Builders' and Contractors' Association. In view of the beneficial work which lies before such an organization, it is most surprising that nothing of the kind exists in this country.

Reading Drawings.

As a rule country builders know very little about draughtsmanship, and care less. Very few farm buildings are put on paper before the work of erection begins, unless the farm is pretty close by a city or town; then the house assumes a somewhat pretentious character, and, when this is the case, the country builder generally fights shy of the contract and the work falls into the hands of the city or town contractor. We see no reason why country builders should not be able to read an architect's drawing just as well as his city rival, and there is no cause for fear on his part of a trained architect exacting more from the countryman than the owner of the building would. Indeed, under the supervision of an architect, the builder stands a much better chance of being fairly dealt with and of giving better satisfaction than would otherwise obtain. If builders in the rural districts would master the art of plan reading, which they can readily do, we fancy they would not have so much prejudice against them or against architects, and they would thereby be in a better position to successfully compete with the town or city contractor on work in their own neighborhood a condition worth striving for.

Damp Courses.

If proper steps are taken when a foundation is laid which is intended to carry a brick or stone superstructure, there will never be any dampness in the walls above the lower joists. A "damp course" of slate should be laid in the wall across the whole thickness, under the first tier of joists, and should be well bedded in with neat Portland cement. If slates can not be obtained a thick coat of asphalt mortar may be used on top of the stone work on which the brickwork may start; if well done, the asphalt will prevent dampness from rising in the walls. If neither slates or asphalt is obtainable then it will be well to finish the top of the wall with a coat of "neat" Portland cement, and to lay the first two or three courses of bricks in cement mortar. This latter method is by no means a sure success, but, if adopted, it will do much towards keeping the upper walls dry. We have known sheet lead to be used on walls as a damp arrester and it was a decided success, but costly, and not by any means lasting. It is said that just below the line of earth around the base of the Cathedral of Cologne, sheet copper was laid on the walls for the purpose it is supposed of preventing dampness ascending the walls, which it has effectually done, and in the joints under the massive towers of the Cathedral where the copper was placed, the weight above has settled on the copper with such a pressure that the metal has actually oozed out of the joints and formed a solid copper bead which runs all round the foot of the towers, inside and out. No brick or stone building should be erected, particularly in the rural districts, without being fully protected by a "damp course."

Laying Base.

There are many places where it is the height of folly to put down base or wainscotting after the floors are laid. Take kitchens for instance: Here a floor is scarcely ever carpeted, and it is more used perhaps than any other floor in a house, and, this being the case, it is only a matter of time, and a very short time at that, before the floor will be so badly worn that a new floor will be absolutely necessary. Now, if the old floor is to be taken up and in nine cases out of ten such will be the result then the base or the lower member of the wainscot must be taken off the wall, a process that is difficult and fraught with danger to the wall and to the wood-work removed, as if is likely to be split, broken, or so badly shattered as to be unfit for use again. To avoid all this, in rooms in which the floors are likely to be much used and quickly worn out, a rough floor should be laid down first, and then the base or wainscotting should be put down, the lowest member fitting down to the rough flooring; then the top or finishing floor should be put down tight between the base boards. In the angle where the floor adjoins the base, an ovolo or quarter-round should be nailed well on the floor, which will have a tendency to keep the floor warm. When it becomes necessary to take the floor up, it may readily be done by removing the ovolo moulding which may be used again when the old flooring can be torn up without removing or injuring the base boards in the slightest. It is an awkward job to tear up an old floor and put down a new one, if all the base boards have to

be taken down and put in place again when the new floor is completed, and often the plasterer has to be called in to mend and patch the broken walls after the carpenter is through, and following in the heels of the plasterer comes the painter, who is obliged to repaint the whole base or wainscot, in order to cover over the splits, cracks and patches the carpenter left behind, and all because the base had been laid after the floors were down instead of being laid down before the finishing floor went down.

Painting Floors.

It is not an uncommon thing for a painter to be asked to paint a floor, and generally he is instructed as to the color and other little matters. If the floor is one that will be subject to much wear and is to be painted with oil paint, the workman should select such coloring substances of certain earthy matters only, for the use of white lead for this purpose is a mistake that should be avoided. Most people advocate the use of lead in painting floors because of its supreme density and body, under the mistaken idea that density adds to its wearing quality. As a matter of fact, no oil paint will stand less wear than white lead, or colors composed largely of white lead. It simply covers the surface, and is one of the best paints employed to protect wood-work, where there is no great wear. Ochres make the best wearing paints, and they may be applied in several ways. They may be mixed with the oil and applied with a brush in the usual way, or they may be applied when mixed with hot stale beer and glue water, and when dry two coats of oil may be laid on thinly with a good strong brush, and if properly done the work will be lasting and satisfactory. In every case the floor should be perfectly clean and dry, before the color is applied, and if the latter is mixed with the oil, the floor should receive two coats, both of which should be well brushed in. If it is desired that the floor should present a varnish-like lustre, the following may be employed, which answers the double purpose of making the paint more durable and adding the polish: Dissolve two parts of shellac in eight parts of alcohol of about eighty per cent., and add to it one quarter of a part of camphor. When the whole is completely dissolved, it can be filtered or strained through a cloth in order to separate the suspended impurities. Paint the floor with this composition once or twice as may be required, and it may then be rubbed over with a soft cloth on which a little sweet oil has been applied, when a surface will be obtained that will be hard and glossy. When this top coating has been partly worn off, another application of the shellac mixture will restore it to its shiny condition.

Sham Competition.

There is a species of competition practised by owners, and often winked at by architects, which, while not exactly dishonest, is somewhat fishy, and it would be better for all parties concerned if the practice was "stamped out" entirely. Estimates are called for on certain work from a member engaged in the calling pertaining to it, but the particular friend of the owner, or of someone deeply interested, is given a sly glance at the figures of his rivals, with the suggestion that the lowest bidder is to get the work. The favorite always understands what this means, and generally so modifies his original demand that he gets the contract. All really honest men will deprecate this form of confidencing the unsuspecting tenderers out of the contracts which they have justly earned by the recognized rules governing fair competitions. A favorite may have a certain claim for preference so long as his bid is as low as the lowest; but by what law of selection can he be chosen over those who put in lower original tenders for the same work with the implied understanding that all the contestants stood on an equal footing. This sort of sham competition is done every day by men who consider themselves as good and as honest as the best, and who would instantly resent any insinuations that reflected on what the world would term their honesty. True, there is generally a clause inserted in the advertisement asking for tenders which states, "that the lowest or any tender not necessarily accepted." But this clause is inserted in order to protect the owner against incompetent and irresponsible contractors, not for the purpose of "cheese-paring" the tenders, and therefore has no force in cases similar to those under notice. Aside from the injury to the party rightfully entitled to the contract, the parties to the deception are placed in such relations to each other that the letter of the specifications cannot be rigidly enforced as when the competition has been fair and open. The contractor feels that, as his own price was not given him, little slights in the execution of the work should not be complained of, and the owner, recognizing the force of this agreement, lets the matter pass. There is another thing in connection with this "sham contracting" that has a baleful effect. It has the effect of reducing the wages of the workmen, and of rushing the work through by driving the men at a steam engine pace, and it generally results in unsatisfactory workmanship and the introduction of inferior materials.

SETTLEMENT OF THE LONDON STRIKE.

The great strike in the building trades in London, Eng., in which 10,000 workmen were engaged, has been settled, as the result of a conference between representatives of the unions and the Central Association of Master Builders. An advance of ½d. per hour for plasterers, bricklayers, carpenters, mill-sawyers, and wood-cutting machinists, and a code of working rules for the future, has been agreed upon. The laborers refused an advance of ¼d. on the same terms, but returned to work at the old rate of wages. The agreement provides that unionists and non-unionists shall work amicably together, and that no dispute shall be undertaken until it has been referred to a joint committee of employers and workmen.

MASTER PLUMBERS' OUTING.

The union pic-nic of master plumbers and their friends held at Mountain View Park, Hamilton, on the 31st ultimo, was a most enjoyable affair. The representation from Toronto and Hamilton was quite large, the plumbers of the latter place having closed their places of business for the day. London, Sarnia, St. Catharines, Brantford and Guelph were also well represented, and in all over three hundred enjoyed the day's recreation. Among the usual sports was a baseball match between Toronto and Hamilton master plumbers, in which the Toronto contingent suffered defeat.

Mr. W. J. Burroughes, president of the Toronto Master Plumbers' Association, reports a steady increase in the membership thereof. At the last meeting no less than twelve new members were added to the roll, several being from adjacent towns.

STONE CRUSHER OPERATED BY ELECTRICITY.

THERE has recently been installed at Peterboro, by the Royal Electric Company, an electric motor for operating a stone crusher, used by Messrs. Corry & Laverdure, contractors for the construction of the Trent Valley Canal, to crush all stone required for that section of the canal. The plant is said to be the first of the kind and the only one in commercial operation in Canada.

The current to operate the stone crusher is transmitted from the station of the Peterboro Light and Power Company, a mile distant. The motor plant consists of a fifty kilowatt alternating current synchronous motor, with its exciter, and a five horse power starting motor. The alternating current is taken by the motor directly from the transmission line at 1,000 volts. The stone crusher is belted to one end of the shaft of the synchronous motor, to the other end being belted in tandem the exciter and starting motor.

To indicate to the attendant on the stone-crushing plant the proper time to connect the synchronous motor with the alternating current transmission line from the station, a synchronizer is used, which consists simply of two transformers, so connected that when the synchronous motor is at the required speed and in step with the generator, a mile away, a lamp connected with these transformers goes out, giving positive indication to the attendant when to connect the motor with the transmission line.

The plant was started June 17th and the stone crusher has been successfully doing its work every day. It has been put to the utmost test; the greatest possible loads have been put on; the crusher has been jammed full of the hardest stones obtainable; the greatest variations possible in load, from nothing to the extreme capacity of the crusher, have taken place rapidly, but no variation in speed occurred, the synchronous motor meeting every demand upon it without change.

Messrs. Corry & Laverdure express themselves as pleased with the operation of the plant.

THE USE OF QUANTITY SHEETS IN PLUMBING.

MR. F. HORTON, contractor, of Montreal, writes as follows to the Plumbers' Trade Journal advising the use of quantity sheets in figuring on plumbing, heating, and electric lighting:

I enclose you a copy of plumbing, heating and electric and gas fitting quantities, which you may make public in your valuable paper, and which I claim has been much needed in the contracting business. The cost of the quantity sheets is very little more than ordinary paper. It takes less room in your pocket than a book would, and is also a memory refresher, by the notes being printed on the sheets, which leads you to examine the specification more closely. Also, you can tear one of the sheets from the pad which you carry, hand it to your bookkeeper, who needs no further explanations, thereby leaving you more time for other business.

I wish to say there have been many contracts taken below cost in Montreal by mistakes being made in taking quantities of the plans and specifications. I know of instances when the brother contractors have assembled and discussed about the successful contractor taking the contract below cost of their tenders, and the successful contractor at the same time felt sure he had made a good living profit on his price tendered to the architect. But on the completion of job, all charges being in for labor and material against the contract, he found that he was a loser of some hundreds of articles through leaving out by mistake things specified by not having a quantity sheet or memory refresher, which is, no doubt, the cause of so many jobs taken low.

I can scarcely understand that any sane contractor will take a job below cost. There is nothing in my estimation for a contractor to gain by doing ten thousand dollars worth of business which has cost him ten thousand five hundred. He has lost one year of his life and five hundred dollars in cash. He is a sadder and a wiser man than before he signed his contract, and may have to make arrangements with his creditors, and lose his honorable name, by not paying a hundred cents on the dollar.

The Master Plumbers' Association of St. John, N. B., and vicinity held a meeting on the 7th inst., at which the following officers were elected for the ensuing year: President, Thomas Campbell, St. John; 1st vice-president, J. H. Doody; 2nd vice-president, Hamilton Kitchen, Fredericton; secretary-treasurer, Peter Campbell, St. John.

THE CAUSE OF INSANITARY DWELLINGS.

A COMMISSION appointed by the London Lancet to inquire into the cause of the prevalence of insanitary arrangements and bad plumbing in dwellings, assigns for these three principal reasons, viz.: (1) The prevailing indifference and consequent ignorance of all classes as to the various sanitary appliances by which they are surrounded; (2) the bad work and cheap materials put in many houses by either unqualified or unscrupulous men, encouraged by a dangerous practice of putting such work up to tender, and (3) the cost of rectifying insanitary work. The first of these causes is, we believe, the foundation one. The majority of people will not take the trouble to study the principles of sanitation to the degree necessary to reveal to them its important bearing upon health and life. Knowing nothing about the subject, they do not trouble themselves about dangers which are not visible to the naked eye, but rather concern themselves with the outward and inward appointments of the house, and accept by faith the assurance that the drains are all right. If the public would wake up on this question, and be as particular about the sanitary as about the other appointments of the houses they live in, there would be seen an immediate improvement in the character of plumbing work. Great advancement has been made within the past decade as the result of efforts of local boards of health and municipal enactments. It is to the credit of the leading plumbers in Canada that they have always shown themselves eager to assist the public bodies in bringing about improved conditions, and the recently organized Dominion Master Plumbers' Association has avowed this to be the principal object of its existence.

PIC-NIC OF LONDON BUILDERS.

THE fifth annual pic-nic of the builders of London, Ont., was held at Port Stanley on Saturday, the 8th inst., and proved quite as enjoyable as any of its predecessors. There were present nearly 2,000 persons who were connected with the several trades in the building line. The games and sports were a feature of the day. The judges appointed were Messrs. W. Skelly, E. Fitzgerald, Geo. Tambling, Geo. Riddle, J. G. Pritchett and H. C. McBride. Races were arranged for the members of the several trades, and lively contests were witnessed. A baseball match was also played between two picked teams. The general committee in charge of the arrangements comprised:—Chairman, Wm. Smith; treasurer, John Nicol; secretary, Walter Toll, and Messrs. R. Lewis, N. Graham, J. Quick, H. Boyer, J. Eggett, Thomas Rich, W. Pring, W. Burleigh, J. Boon, L. Stevenson, B. Sage, J. Walker, T. Irwin, G. Rougley, W. Bennett, J. Pritchart, W. Stone, and Ed. Hunter.

MODERN PRACTICE IN INTERIOR WIRING.

IN the course of his paper on the "Evolution of Interior Conduits from the Electrical Standpoint," before the National Electric Light Association at New York, Luther Stieringer made the following statement:

The best experience in the past fifteen years in interior wiring has demonstrated the following facts:

First—Indiscriminate wiring with staples is universally condemned.

Second—Cleat wiring is admissible in exposed work where the circumstances admit, but not in concealed work.

Third—Wires imbedded in plaster, depending on the insulation only for protection, are condemned.

Fourth—Lead-covered wires are also condemned, except where protected in a conduit.

Fifth—Wires in mouldings do not afford mechanical or chemical protection, and are only admissible in surface work.

Sixth—Wires carried in plaster, and covered with split or zinc tubes to prevent injury by trowels, are condemned.

Seventh—Glass or porcelain insulators can only be utilized in special cases of exposed work.

Eighth—Paper tubes do not afford absolute mechanical and chemical protection.

Ninth—Insulated tubes covered with a thin coating of brass or other metals do not afford absolute mechanical and chemical protection, but in exposed work they are to a certain extent admissible.

Tenth—Woven fabric conduit does not afford absolute chemical protection.

Eleventh.—Heavy insulating covering, integral with the insulation, offers no absolute protection against mechanical and chemical injury, and is analagous to rubber tubing for gas distribution installed throughout a building.

Twelfth—Concentric wiring is practiced in England with satisfactory results, but it is not in use in the United States. It offers many possibilities in the direction of a solid and fixed system.

Thirteenth—Paper-lined iron or steel pipes, known as "iron-armored conduit," "builders' tube," "armorite," "Clifton," and plain iron or steel pipe, are the only conduits that can afford absolute security against mechanical and chemical injury and assure permanence.

"TIPS" FOR BUILDERS.

NEVER compete with a "botch" if you know he is favored by the person about to build. He will undercut and beat you every time. Old material should never be destroyed simply because it is old.

When putting away old stuff see that it is protected from rain and atmosphere.

It costs about 15 per cent. extra to work up old material, and this fact should be borne in mind, as I have known several contractors who paid dearly for their "whistle" in estimating on working up second-hand material.

These remarks apply to woodwork only. In using old brick, stone, slate, and other miscellaneous materials it is well to add double price for working up.

Workmen do not care to handle old material, and justly so. It is ruinous to tools, painful to handle, and very destructive to clothing.

In my experience I always found it paid to advance the wages of workmen—skilled mechanics—while working up old material. This encouraged the men and spurred them to better efforts.

Sash frames, with sash weights, locks and trim complete, may be taken out of old buildings that are being taken down and preserved just as good as new by screwing slats and braces on them, which not only keeps the frame square, but prevents the glass from being broken.

Doors, frames and trims may also be kept in good

STONE CRUSHER OPERATED BY ELECTRICITY.

THERE has recently been installed at Peterboro, by the Royal Electric Company, an electric motor for operating a stone crusher, used by Messrs. Corry & Laverdure, contractors for the construction of the Trent Valley Canal, to crush all stone required for that section of the canal. The plant is said to be the first of the kind and the only one in commercial operation in Canada.

The current to operate the stone crusher is transmitted from the station of the Peterboro Light and Power Company, a mile distant. The motor plant consists of a fifty kilowatt alternating current synchronous motor, with its exciter, and a five horse power starting motor. The alternating current is taken by the motor directly from the transmission line at 1,000 volts. The stone crusher is belted to one end of the shaft of the synchronous motor, to the other end being belted in tandem the exciter and starting motor.

To indicate to the attendant on the stone-crushing plant the proper time to connect the synchronous motor with the alternating current transmission line from the station, a synchronizer is used, which consists simply of two transformers, so connected that when the synchronous motor is at the required speed and in step with the generator, a mile away, a lamp connected with these transformers goes out, giving positive indication to the attendant when to connect the motor with the transmission line.

The plant was started June 17th and the stone crusher has been successfully doing its work every day. It has been put to the utmost test; the greatest possible loads have been put on; the crusher has been jammed full of the hardest stones obtainable; the greatest variations possible in load, from nothing to the extreme capacity of the crusher, have taken place rapidly, but no variation in speed occurred, the synchronous motor meeting every demand upon it without change.

Messrs. Corry & Laverdure express themselves as pleased with the operation of the plant.

THE USE OF QUANTITY SHEETS IN PLUMBING.

MR. F. HORTON, contractor, of Montreal, writes as follows to the Plumbers' Trade Journal advising the use of quantity sheets in figuring on plumbing, heating, and electric lighting:

I enclose you a copy of plumbing, heating and electric and gas fitting quantities, which you may make public in your valuable paper, and which I claim has been much needed in the contracting business. The cost of the quantity sheets is very little more than ordinary paper. It takes less room in your pocket than a book would, and is also a memory refresher, by the notes being printed on the sheets, which leads you to examine the specification more closely. Also, you can tear one of the sheets from the pad which you carry, hand it to your bookkeeper, who needs no further explanations, thereby leaving you more time for other business.

I wish to say there have been many contracts taken below cost in Montreal by mistakes being made in taking quantities of the plans and specifications. I know of instances when the brother contractors have assembled and discussed about the successful contractor taking the contract below cost of their tenders, and the successful contractor at the same time felt sure he had made a good living profit on his price tendered to the architect. But on the completion of job, all charges being in for labor and material against the contract, he found that he was a loser of some hundreds of articles through leaving out by mistake things specified by not having a quantity sheet or memory refresher, which is, no doubt, the cause of so many jobs taken low.

I can scarcely understand that any sane contractor will take a job below cost. There is nothing in my estimation for a contractor to gain by doing ten thousand dollars worth of business which has cost him ten thousand five hundred. He has lost one year of his life and five hundred dollars in cash. He is a sadder and a wiser man than before he signed his contract, and may have to make arrangements with his creditors, and lose his honorable name, by not paying a hundred cents on the dollar.

The Master Plumbers' Association of St. John, N. B., and vicinity held a meeting on the 7th inst., at which the following officers were elected for the ensuing year: President, Thomas Campbell, St. John; 1st vice-president, J. H. Doody; 2nd vice-president, Hamilton Kitchen, Fredericton; secretary-treasurer, Peter Campbell, St. John.

THE CAUSE OF INSANITARY DWELLINGS.

A COMMISSION appointed by the London Lancet to inquire into the cause of the prevalence of insanitary arrangements and bad plumbing in dwellings, assigns for these three principal reasons, viz.: (1) The prevailing indifference and consequent ignorance of all classes as to the various sanitary appliances by which they are surrounded; (2) the bad work and cheap materials put in many houses by either unqualified or unscrupulous men, encouraged by a dangerous practice of putting such work up to tender, and (3) the cost of rectifying insanitary work. The first of these causes is, we believe, the foundation one. The majority of people will not take the trouble to study the principles of sanitation to the degree necessary to reveal to them its important bearing upon health and life. Knowing nothing about the subject, they do not trouble themselves about dangers which are not visible to the naked eye, but rather concern themselves with the outward and inward appointments of the house, and accept by faith the assurance that the drains are all right. If the public would wake up on this question, and be as particular about the sanitary as about the other appointments of the houses they live in, there would be seen an immediate improvement in the character of plumbing work. Great advancement has been made within the past decade as the result of efforts of local boards of health and municipal enactments. It is to the credit of the leading plumbers in Canada that they have always shown themselves eager to assist the public bodies in bringing about improved conditions, and the recently organized Dominion Master Plumbers' Association has avowed this to be the principal object of its existence.

PIC-NIC OF LONDON BUILDERS.

THE fifth annual pic-nic of the builders of London, Ont., was held at Port Stanley on Saturday, the 8th inst., and proved quite as enjoyable as any of its predecessors. There were present nearly 2,000 persons who were connected with the several trades in the building line. The games and sports were a feature of the day. The judges appointed were Messrs. W. Skelly, E. Fitzgerald, Geo. Tambling, Geo. Riddle, J. G. Pritchett and H. C. McBride. Races were arranged for the members of the several trades, and lively contests were witnessed. A baseball match was also played between two picked teams. The general committee in charge of the arrangements comprised: Chairman; Wm. Smith; treasurer, John Nicol; secretary, Walter Toll, and Messrs. R. Lewis, N. Graham, J. Quick, H. Boyer, J. Eggett, Thomas Rich, W. Pring, W. Burleigh, J. Boon, L. Stevenson, B. Sage, J. Walker, T. Irwin, G. Rougley, W. Bennett, J. Pritchart, W. Stone, and Ed. Hunter.

MODERN PRACTICE IN INTERIOR WIRING.

IN the course of his paper on the "Evolution of Interior Conduits from the Electrical Standpoint," before the National Electric Light Association at New York, Luther Stieringer made the following statement:

The best experience in the past fifteen years in interior wiring has demonstrated the following facts:

First—Indiscriminate wiring with staples is universally condemned.

Second—Cleat wiring is admissible in exposed work where the circumstances admit, but not in concealed work.

Third—Wires imbedded in plaster, depending on the insulation only for protection, are condemned.

Fourth—Lead-covered wires are also condemned, except where protected in a conduit.

Tenth—Woven fabric conduit does not afford absolute chemical protection.

Eleventh.—Heavy insulating covering, integral with the insulation offers no absolute protection against mechanical and chemical injury, and is analagous to rubber tubing for gas distribution installed throughout a building.

Twelfth—Concentric wiring is practiced in England with satisfactory results, but it is not in use in the United States. It offers many possibilities in the direction of a solid and fixed system.

Thirteenth—Paper-lined iron or steel pipes, known as "iron-armored conduit," "builders' tube," "armorite," "Clifton," and plain iron or steel pipe, are the only conduits that can afford absolute security against mechanical and chemical injury and assure permanence.

"TIPS" FOR BUILDERS.

NEVER compete with a "botch" if you know he is favored by the person about to build. He will undercut and beat you every time. Old material should never be destroyed simply because it is old.

When putting away old stuff see that it is protected from rain and atmosphere.

It costs about 15 per cent. extra to work up old material, and this fact should be borne in mind, as I have known several contractors who paid dearly for their "whistle" in estimating on working up second-hand material.

These remarks apply to woodwork only. In using old brick, stone, slate, and other miscellaneous materials it is well to add double price for working up.

Workmen do not care to handle old material, and justly so. It is ruinous to tools, painful to handle, and very destructive to clothing.

In my experience I always found it paid to advance the wages of workmen—skilled mechanics—while working up old material. This encouraged the men and spurred them to better efforts.

Sash frames, with sash-weights, locks and trim complete, may be taken out of old buildings that are being taken down and preserved just as good as new by screwing slats and braces on them, which not only keeps the frame square, but prevents the glass from being broken.

Doors, frames and trims may also be kept in good

v.8-9
Canadian
archi

order until used, by taking the same precautions as in window frames.

Old scantlings and joists may have all nails drawn or hammered in before piling away.

Counters, shelving, drawers and other store fittings should be kindly dealt with. They will be wanted sooner or later.

Take care of the locks, hinges, bolts, keys, and other hardware. Each individual piece represents money in a greater or lesser sum.

Old flooring can seldom be utilized, though I have seen it used for temporary purposes, such as fencing, covering of veranda floors while finishing work on plastering, etc. As a rule, however, it does not pay to take it up carefully and preserve it. Conductor pipes, metallic cornices, and sheet metal work generally, can seldom be made available a second time, though all is worth caring for, as some parties may use it for repairs.

Sinks, wash-basins, bath-tubs, traps, heating appliances, grates, mantels and hearth-stones should be moved with care. They are always worth money and may be used in many places as substitutes for more inferior fixings.

Marble mantels require the most careful handling.

Perhaps the most difficult fixings about a house to adapt a second time are the stairs. Yet I have known where a man has so managed to put up new buildings that the old stairs taken from another building just suited. This may have been a "favorite accident," but the initiated reader will understand him. Seldom such accidents can occur.

Rails, balusters and newels may be utilized much readier than stairs, as the rails may be lengthened or shortened to suit variable conditions.

Gas fixtures should be cared for and stowed away in some dry place. They can often be made available, and are not easily renovated if soiled or tarnished.

It is not wise to employ men who have nothing but their strength to recommend them. As a rule they are like bears—have more strength than knowledge, and lack of the latter is often an expensive desideration. Employ for taking down the work good careful mechanics, and do not have the work "rushed through." Rushers of this sort are expensive.

Never send old material to a mill to be sawed or planed, no matter how carefully nails, pebbles and sand have been hunted for; the saw or planer knives will most assuredly find some you overlooked; then there will be trouble at the mill.

Have some mercy for the workman's tools. If it can be avoided do not work up old stuff into fine work. If not avoidable pay the workman something extra because of injury to tools.

Don't grumble if you do not get as good results from the use of old material as from new. The workman has much to contend with while working up old nail-speckeled, sand-covered material.

WHEN CARVING SHOULD BE EXECUTED.

It would be interesting to learn, says the Scientific American, just why so many stone carvers prefer to work on the material after it has been built into a structure rather than on the block before placing. When interrogated as to this preference the usual answer is that it is thus easier to match the cutting on adjoining blocks, or that one gets a better idea of the effect in this way. Or perhaps it may be argued that there is danger of damage to delicate reliefs in handling the blocks and getting them into position. Yet neither or all of these appear to be sufficient reasons—sufficient, that is, to offset the disadvantage of working in awkward positions, of not having spare tools handy, and of the danger of mutilation of a placed stone by a slip. As to the latter, which would apparently be a very serious and expensive matter usually, one carver, whose specialty is scroll and leaf cutting, medallions, pilaster and column capitals, etc., says that he can generally get over or conceal small breaks by slightly altering the design. But, after all, the practice does not seem reasonable, and none of the explanations are quite satisfying. Of course, there are cases where there is no choice, but for the most part the ornamental work could, it would seem, be done to better advantage in the yard or under cover than when the workman is slung up on a staging. All the delicate reliefs, even in limestone and sandstone, or soft material in general, could be crated and otherwise protected for handling in setting up.

Both systems seem to have been followed by the ancient Egyptian and Greek cutters, though it is not always easy to determine the method. From what is known of the skill of the old constructors in getting heavy material into place, making close joints and perfect matching, it may be concluded that a large part of the carving was done before erection. We degenerate moderns, too, have some tricks of our own, going so far now in good practice as to have pressed and ornamental bricks snugly packed in crates at the brickyards, transported in these crates, and finally swung up in them to the level where the bricks are to be set, and not for convenience in handling merely, but to avoid chipping of corners and edges, thus effecting quite a little saving. Finished stone also can be protected against rough usage in transportation, as is being done daily everywhere.

It was suggested to an expert carver who favored the plan of working on the building rather than on the unassembled parts of it, that his preference was perhaps only the outcome of convention and habit, and it was delicately intimated that possibly he had not even considered the matter seriously. But he would not have it that way at all, though he could not make the meddlesome outsider understand why he liked to work lying down or doubled up rather than in the normal posture of other artisans.

PERSONAL.

The death is announced of Mr. Wm. Cain, a prominent contractor of St. John, N. B.

Mr. Charles Crane, contractor, formerly of St. Thomas, Ont., met his death at Sault Ste. Marie by falling from a building.

Hamilton Kitchen, of the firm of Kitchen & Shea, plumbers, Fredericton, N. B., had his arm dislocated recently in a collision while riding his bicycle.

Mr. August Prestien, contractor, of Hespeler, was accidentally killed while stepping from the motor car to the trailer on the Galt, Preston and Hespeler electric railway. Deceased was a prominent citizen of the town, and had also served as municipal councillor.

Mr. Frank H. Doty, of the Doty Engineering Works, and President of the Toronto Dredging & Contracting Co., Toronto, was accidentally killed while engaged on a dredge at the island. He was standing on the platform of the dredge directing the movements of the scoop, when the big wheel slipped a cog and the iron bar swung suddenly around, striking him on the head.

BUILDER'S ESTIMATES.*

STONE-WORK is estimated by the perch; 24¾ cubic feet making one perch. An 18-inch wall, 1 foot high, and 16½ feet long, contains one perch.

BRICK-WORK.—Bricks are usually estimated at 25 to the cubic foot. They usually lay 5 courses to each foot in height.

For an 8-inch wall, allow 17 bricks for each square foot of surface. For a 12-inch wall, allow 25 bricks for each square foot of surface. For a 16-inch wall, allow 34 bricks for each square foot of surface.

CHIMNEYS.

Size of Chimney.	No. of Flues.	Size of Flues.	No. of Bricks per foot in Height
16 × 16 inches	1	8 × 8 inches	30
16 × 24 "	1	8 × 16 "	40
16 × 28 "	2	8 × 8 "	50
16 × 40 "	3	8 × 8 "	70
16 × 52 "	4	8 × 8 "	90
20 × 20 "	1	12 × 12 "	40
20 × 24 "	1	12 × 16 "	45

The above does not include waste, which must be allowed.

MORTAR FOR BRICK-WORK. One cask of good lime to a load (about 20 bushels) of sand is sufficient for 1,000 or 1,100 bricks.

CEMENT FOR CELLAR BOTTOMS should be mixed in the proportion of 1 of cement to 3 of gravel, and should be laid 3 inches thick. One cask of cement will cover five or 6 square yards.

PLASTERERS' MORTAR. One cask of lime to a load (20 bushels) of sand, and 2 bushels of hair, will cover about 50 square yards of surface; and ½ cask of lime will skim the same. In estimating the surface to be covered, plasterers deduct only half the area of openings, such as doors and windows, from the square yards in the walls.

TIMBERS.

TIMBERS FOR A LIGHT FRAME. Sills, 4 x 6 or 6 x 6 inches. Flooring-timbers, 2 x 6 inches, put from 16 to 22 inches apart. Posts, 3 x 5 inches. Ledger-boards, 1 x 6 inches, well fitted and nailed. Studding, 2 x 3 inches, put 16 inches to centres. Plates, 3 x 4 inches. Rafters, 2 x 5 inches, put 2 feet apart. Partition studding, 2 x 3 and strapping 1 x 3 inches, put 16 inches to centres.

TIMBERS FOR A MEDIUM FRAME. Sills, 6 x 7, 7 x 8, or 8 x 8 inches. Flooring-timbers, 2 x 8, 9, or 10 inches, put 16 or 18 inches apart, and bridged. Posts, 4 x 6 or 4 x 8 inches. Studding, 2 x 4 inches, put 16 inches to centres. Window and door studs, 3 x 4, or 4 x 4 inches. Ledger-boards, 1 x 7 or 8 inches, well fitted and nailed, or girts, 4 or 5 x 7 or 8 inches. Plates, 3 x 4 inches. Rafters, 2 x 6 inches, put 2 feet apart. Main partition studs 2 x 4 inches; other partitions, 2 x 3 inches, put 12 or 16 inches to centres.

TIMBERS FOR A GOOD HEAVY FRAME FOR DWELLING-HOUSE. Sills, 8 x 8 or 8 x 10 inches. Flooring-timbers, first story, 2 x 12 inches; second story, 2 x 10 inches; third story, 2 x 8 inches, put 16 or 18 inches apart, and well bridged. Side girts, 5 x 8 inches. End girts, 6 x 8 inches. Outside studding, 2 x 5 inches, put 12 or 16 inches to centres. Window and door studs, 3 x 5 inches. Rafters, 2 x 8 inches, put 20 or 24 inches apart. Main partitions, 2 x 5 inches; other partitions, 2 x 4 inches, put 12 or 16 inches to centres.

To square the sills of a house, make a mark on the upper outside edge of the side sill 8 feet from the corner of the house, and 6 feet from the corner of the house on the end sill; when the sills are square, a 10-foot pole will just reach across from point to point.

FRAMING AND BOARDING. To estimate the number of square feet of boards required to board a building, and lay the under floors, double the length, and also the width of the building; add these amounts, which gives the length around the building; multiply this by the length of the outside studding, which gives the square feet in the walls of the house. If the house has a pitch roof, multiply the width of the house by the rise of the roof: the result will be the square feet in 2 gables. Then, to find the square feet in the roof: to the length of the house, add the amount of projection at both ends (generally about 18 inches at each end, which makes 3 feet to be added), which amount multiply by twice the total length of the rafters, which gives the square feet in the roof. Then for the floors, multiply the length of the building by the width, and multiply this by the number of floors, which gives the square feet in all of the floors. Add together these different amounts, and add ⅛ for waste, which will give the number of square feet required. In estimating the labor in framing and boarding, some builders reckon eight or ten dollars per thousand feet.

*From "Modern Carpentry and Building," by Allen Sylvester.

WIRE AND CUT NAILS.

SOME experiments were recently made to determine the comparative holding power of wire and cut nails. The tests were made on pieces of white pine, joined with simple lap joints fastened by the nails. These were subject to transverse stresses, in some cases parallel to the axes of the nails, in others at right angles. When the load was applied perpendicular to the nails, the wood was often split and the cut nails were often broken, while the wire nail joints were broken by bending and drawing the nails. When the load was applied in the direction in which the nails were driven, the joints were broken by nails being drawn almost without being bent. Under this same manner of loading, the wire nails were started by smaller loads than the cut nails, yet when the cut nails were started they yielded rapidly, while the wire nails held nearly as well as at first. In all the cases tried the cut nails were found superior in strength and rigidity, while in one-half the cases wire nails gave the joints greater resistance than cut nails.

USEFUL HINTS.

All dark colour pigments, being but slightly basic in their nature, require more oil in their preparation than light colours. It is noticed in picture and portrait paintings that the cracks in the paint are far more numerous in the dark colours (not blacks) than in the white or light colours.

PAINT FOR IRONWORK.—Professor J. Spennrath gives in the Deutsches Bauzeitung an account of some interesting researches which he has made relative to the value of paints for ironwork. As one result of these, the professor concludes that none of the metallic oxides commonly used combine chemically with linseed oil. The drying process depends exclusively on an absorption of oxygen in a purely mechanical way. The value of the different pigments used varies. Thus zinc white, when used for outside work, rapidly swells to double its previous volume, owing to the absorption of carbonic acid gas and water. Sulphuretted hydrogen will cause red or white lead to act in a similar way, but, when pure, Professor Spennrath considers these two latter pigments satisfactory. Carbon paints are very stable, as is heavy spar, but the covering power of the latter is small. In order to test the relative durability of various paints, sheets of zinc were coated with a number of different kinds. The zinc was then dissolved away by acid, leaving a film of paint. All these films, it was found, could be destroyed by the action of dilute nitric or hydrochloric acids, while the vapours of sulphuric and acetic acids acted similarly. Alkaline fluids and gases also destroyed the paints rapidly. Pure water was found to be more injurious than salt water, and hence the destructive action of sea water is to be attributed mainly to the mechanical effects of wash. Hot water was found to act more rapidly than cold. The most important discovery made was, however, the great influence of temperature. Films, similar to those already described, completely lost their elasticity and became brittle when exposed to a temperature of 203 degrees Fahrenheit. There was, at the same time, a large contraction.

Mr. W. A. Sylvester, of Boston, Mass., has published under the title "Modern Carpentry and Building," a revised edition of his "Carpenter's Companion." It treats of framing and stair building, builders' estimates, sizes, weights and strength of materials, house planning, etc. We are indebted to Messrs. Damrell & Upham, 283 Washington street, Boston, for a copy of the work.

The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.
Prices for advertisements sent promptly on application. Orders for advertisemnets should reach the office of publication not later than the 12th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.
Contributions of value to the persons in whose interest this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publisher of any irregularity in delivery of paper.

ONTARIO ASSOCIATION OF ARCHITECTS.

OFFICERS FOR 1896.

PRESIDENT	H. B. GORDON, Toronto.
1ST VICE-PRESIDENT	J. GEMMELL, Toronto.
2ND VICE-PRESIDENT	JOS. W. POWER, Kingston.
TREASURER	EDMUND BURKE, Toronto.

COUNCIL:

F. J. ALEXANDER	Ottawa.
THOS. FULLER	Ottawa.
E. J. LENNOX	Toronto.
J. M. MOORE	London
W. R. STRICKLAND	Toronto

REGISTRAR AND LIBRARIAN:
W. A. LANGTON - Canada Life Building, Toronto.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.

OFFICERS FOR 1896.

PRESIDENT	A. T. TAYLOR, F.R.I.B.A., Montreal.
1ST VICE-PRESIDENT	J. F. PEACHY, Quebec.
2ND VICE-PRESIDENT	A. RAZA, Montreal.
SECRETARY	J. VENNE, Montreal.
TREASURER	E. MAXWELL, Montreal.

COUNCIL:

A. C. HUTCHISON	Montreal.
JAS. NELSON	Montreal.
J. WRIGHT	Montreal.
ROBT. FINDLAY	Montreal.
CHAS. BAILLAIRGE	Quebec.
F. H. BERLINGUET	Quebec.

AUDITORS—G. E. TANGUAY and H. C. NELSON, Montreal.

TORONTO BUILDERS' EXCHANGE.

BOARD OF DIRECTORS:

JOHN ALDRIDGE, President.	JOHN RUSSELL.
THOS. CANNON, Jr., 1st Vice-Pres.	H. LUCAS.
JOHN VICK, 2nd Vice-President.	JOHN YORES.
DAVID WILLIAMS, Treasurer.	JAS. CRANG.
WM. BOOTH.	JOHN M. GANDER.
JOHN WICKETT.	GEORGE HENRY.

JOHN L. PHILLIPS, Secretary.

TO ADVERTISERS.

For the benefit of Advertisers, a copy of this journal is mailed each week to persons mentioned in the CONTRACT RECORD reports as intending to build, with a request to consult our advertisement pages and write advertisers for material, machinery, etc.

Trade Combines.

An agreement has been entered into between the Granite Dealers' Association of Aberdeen, Scotland, and the Boston Wholesale Granite Dealers' Association, whereby the former binds itself not to sell to anyone in the United States who is not a member of the Boston Association, while the latter Association binds itself not to purchase granite from any person outside the membership of the Aberdeen Association. Our recollection is that there are on record instances in which the courts have compelled combines of this character to sell to outsiders who were desirous of purchasing their goods. The legal view appears to be that when an individual or a company engage in the business of publicly selling any material they are bound as far as possible to supply the public demand for such material, or at all events they have not the right to draw a distinction between the would-be purchaser who is a member of a trade organization and one who is not.

Proof of Qualification by Arcbitects and Builders.

The many disasters which have occurred in recent years due to the ignorance and carelessness of persons practising as designers and constructors of buildings, have in some measure directed public attention to the necessity of compelling such persons to give proof of qualification for their important duties. While the efforts put forth by the architects of the State of New York and the Province of Ontario to obtain legislation of this character, have so far failed of their purpose, it is gratifying to know that the necessity of such legislation is becoming more widely recognized, and if those who have been pressing for reform in this direction do not become weary in well doing, there is little doubt that the desired object will be attained in the near future. From the National Association of Building Inspectors convened last month at Buffalo, comes the following resolution on the subject: "That it is the opinion of the National Association of Building Inspectors that public safety demands that persons practising the profession and trade of architect, civil engineer and builder should do so under license, to the end that those who practice such responsible professions and trades should first show their fitness to do so; therefore, we recommend the passage of State laws leading to the accomplishment of this end." Building inspectors are daily brought in contact with the work of incompetent architects and builders, and have the opportunity of knowing, as few can, the danger of loss

to property owners and of health and life to the occupants of buildings erected by these classes. Consequently the pronouncement which has just been made by their association should receive proper consideration from the public and more particularly from the governing bodies.

The A. I. A.

The American Institute of Architects will hold its thirteenth annual convention at Nashville, Tenn., on the 20th, 21st and 22nd inst. A discussion has been arranged for at this convention, on "The Influence of Iron and Steel Construction and of Plate Glass on the Development of Modern Style."

Water Flush and Diameters of Drains.

The Northern Architectural Association in conjunction with officials of the Newcastle and Gateshead Water Company recently made a number of experiments for the purpose of ascertaining the quantity of water required to properly flush a water closet and connecting drains. Also the diameter of drain necessary to insure proper cleansing. These experiments are said to have demonstrated the fact that with proper closets and fittings two gallons of water are sufficient for flushing purposes in dwellings, and that a four inch drain was more perfectly cleansed than a six inch one, notwithstanding that the former contained a more acute bend and was laid at a less steep gradient than the latter. In the principal cities of Canada the use of cast iron pipe for house drains has very properly been made compulsory, and in corroboration of the results of the above mentioned experiments, experience has shown that the most satisfactory results are secured by the use of four inch soil pipe in preference to pipe of larger diameter.

The Location of the Kitchen.

What has become of the idea so prevalent among architects a few years ago, that the top of the house and not the ground floor is the proper location for the kitchen? We recollect how convincingly a Hamilton architect talked on this subject two or three years ago, but we have yet to hear of an instance in which he has put his ideas in practice. The main argument in favor of changing the location of the kitchen in the manner suggested was, that the kitchen odours would find an immediate outlet into the atmosphere instead of being confined and diffused throughout the house. It is to our mind at least a matter of doubt whether the proposed change would secure this desirable result. We know of an office building in which the odor of the cooking from the caretaker's kitchen on the sixth floor at times assails the nostrils of the occupants on every floor, even to the basement. We should be pleased to receive from some of the advocates of the elevated kitchen an explanation regarding this conspicuous failure of their theory.

The P. Q. A. A.

We print in this number an account of the proceedings in connection with the recent annual convention of the Province of Quebec Association of Architects. A perusal of the annual report of the Council shows that an earnest effort has been made during the year by the management of the Association to accomplish a number of very desirable objects. It is to be regretted that in some directions the results achieved have been small owing to failure to get a sufficiently large attendance of the members at the meetings. The enthusiasm which has prompted a few of the leading spirits to stand by the work of the Association in the face of these and other discouragements is highly commendable, and we trust will prove an inspiration to others to give more of their thought and time to the promotion of the Association's welfare. In spite of difficulties the Association has already accomplished a useful work, and has abundantly justified its existence. A much greater work lies before it in the future, and this also will be achieved if every member would feel his individual responsibility to give what assistance is in his power. The establishment of a chair of architecture in McGill University is doubtless in a measure an outcome of the efforts of the Association on behalf of the proper education of future generations of architects, and conversely the Association should derive assistance and support from this department of the university. The City Council of Montreal has shown itself to be alike deficient in gratitude and appreciation of what is due the interests of the citizens, by neglecting to take action upon the recommendations submitted by the Association for the improvement of the building by-laws of the city. A committee of the Association spent months of earnest effort for this object, and it will be a lasting disgrace to the Council if this effort is not recognized and proper consideration given to the recommendations which have been submitted. This statement equally applies to the City Council of Toronto, which is making no effort in the direction of approving or disapproving of the recommendations of the Ontario Association of Architects for the amendment of the city building ordinance. Such treatment is but a poor reward for disinterested efforts in behalf of the public welfare. In connection with the recent convention of the Quebec Association, we miss the papers and discussions on architectural subjects which have usually formed an interesting and instructive feature on similar occasions in the past. Considerable effort and self-sacrifice are certainly involved in the preparation of such papers, but a corresponding benefit is derived by those who hear and read them as well as by the authors themselves from the necessarily thorough study of their subjects. We therefore hope to see this valuable feature re-introduced in the annual conventions of the Association in the future. The Arts and Crafts Exhibition proved an extremely valuable adjunct to the convention, and is well calculated to give public prominence to the Association and its work. There was manifested at the convention a strong desire for the formation of a Dominion Association of Architects. Such an Association, if properly organized and supported should be able to promote in many ways the interests of architecture in the Dominion. In view, however, of the difficulty which is experienced in maintaining the interest of the members in the work of the Provincial Associations we are disposed to doubt the success of a larger organization, the members of which would be scattered from one end of the country to the other. The obvious difficulties in the path of such an organization should be fairly faced and considered before any definite action is taken. If the architects throughout the Dominion would express through our columns their views on the subject, the probable success of the movement could be more easily estimated.

BY THE WAY.

A certain well-known firm whose business it is to manufacture and install heating apparatus were recently advised that one of their plants was not doing satisfactory work. Without showing the least surprise at the information the member of the firm to whom it was addressed, replied in terms like these: "Oh, well, that house was put up by So-and-So, and the heating system is not by any means a fair example of our work. You see, the price was so cut down that it simply was not possible to give the work proper attention." Here we see the evil results of trying to get work done too cheap. The man for whom the system was installed is no longer the owner of the house—in fact he "went down" with many others in the crash which followed the Toronto real estate boom. The present owner in purchasing took it for granted that the heating system was all right because the firm who installed it have a first-class reputation. Aside from the disappointment and discomfort experienced by him as the result of finding that the system is not up to the expected standard, was it wise on the part of the heating contractors to tender at a price which made it impossible for them to do the work properly and maintain their reputation? I have no hesitation in expressing the opinion that it was not, as one such imperfect job is likely to result in future losses exceeding many times in amount the paltry profit which they may have succeeded in squeezing out of the contract.

× × × ×

"There are about half a dozen persons who are not getting their usual amount of sleep these days on account of the contract for heating the new city and county buildings," said a member of a well-known Toronto firm of heating contractors to me the other day. Then he went on to tell me who these persons were, and how the different manufacturers of radiators were working tooth and nail to guide the contract into the hands of their friends who might be depended on to purchase from them the required radiators. My informant remarked that the condition in the specifications requiring that tenderers must show that they have successfully carried out previous contracts of corresponding magnitude, and that they are in a position financially to carry out the work, would be sufficient to narrow the competition down to half a dozen firms at most. "It is a foregone conclusion," said this gentleman, "that the contract will be taken at a low figure, but I think that in view of the many risks involved in a contract of such magnitude, the contractors who successfully complete the work, are entitled and should certainly receive a substantial profit." In answer to my enquiry he expressed the opinion that the work could only be successfully carried out by placing the entire contract in the hands of one firm, and resting the responsibility entirely upon their shoulders. Any attempt at sub-contracting would be sure to lead to confusion and trouble. As an instance of the risk involved in large contracts of this character, my attention was called to the fact that the disagreement into which Mr. Neelon, the contractor for the masonry of this building, fell with the architect, and the extended litigation arising therefrom had caused the contractor's ruin, and that Messrs. Brown & Love, one of the most honorable contracting firms in the Dominion, had suffered the loss of thousands of dollars as the result of their effort to be released from their tender for the completion of the work. "There will be required for this contract," said my friend, "a large number of American specialties, for which 'cash down' must be paid, while the contractor will perhaps be required to wait a long period for payment of his accounts under the contract. He must therefore have a long bank account, and should, as I have already stated, reap a liberal margin of profit from the undertaking." It is understood that the architect has estimated the cost of the heating system for the building at $100,000.

× × × ×

It is by no means an unusual experience to meet with men who cherish original notions regarding the kind of house they would like to build for their comfort. It is well that in the majority of instances these notions never get beyond the form of "castles in the air," for if put in concrete shape the inventor would quickly be disillusionized. If we are to believe a writer in Truth, however, one such individual who happened to be blest with an abundance of "the needful," not only conceived but carried out a decidedly novel idea of house building. We are told that "this man, who has a large lake upon his estate, recently caused it to be drained, and in the deepest part he has had a house built which contains three rooms a smoking-room, a dining room, and a servant's waiting-room. The frame-work of the house is of iron, and the floor is stone resting upon a foundation of concrete. The sides and the roof, however, are entirely composed of very thick plate glass. There is a passage under the water from the boathouse to the glass house, and air is obtained through large clumps of artificial water-lilies which rest upon the surface of the lake. It is indescribably pleasant to sit in one of the rooms upon a warm day; the air is very cool, there is no sound to be heard, and it is especially interesting to watch the fish swimming round, attracted by the glare of the electric lights. This is decidedly a new luxury. The house and the passage, moreover, cost comparatively little to build." If the statement that a house walled and roofed with plate glass, resting on a foundation of concrete and with subaqueous passages, was constructed at comparatively little cost was meant to be taken seriously, we have another proof of the adage, that "Truth is stranger than fiction."

STRENGTH OF GIRDERS.

The Effective Span, for computing the strength of a girder, says the Contract Journal, is the distance between the centres of the bearing areas which support the ends of the girder. The span is usually measured in feet and inches in practice, but for use in computation it is either in feet or parts of a foot, or all in inches. This is according to the nature of the expression (or coefficients) in the formula, as it requires all dimensions $\left(\frac{b\,d^2}{l}\right)$ to be in the same denomination. b, d, l denote the breadth, depth, and length respectively.

As the weight of the girder itself forms a part of its load, hence only the weight per foot run of the clear span between the supports should be taken. The weight of the girder is treated as a uniformly distributed load, and is double that of a centre load.

In computations for obtaining the stiffness of girders, the length of the span and the deflections must be taken as those of the clear span only between supports, and not to the centres of the bearing areas, as required for computations of the strength of girders.

LOADS AND STRENGTH OF ROOFS.

In making estimates of the weights of roofs it is essential that external appendages, such as lantern lights, ventilators, etc., should all be included, as well as ceilings, attic floors, water-tank and water, and any quantity of fixtures, furniture and storage liable to be sustained by the roof supports. All articles and details of the roof structure and the external and internal appendages should be estimated at their maximum weights, so that the gross estimate shall cover all probable strain-producing loads that are likely to be encountered in the use of the building. In addition to these dead loads there should, in the case of occupied atties, be an allowance for the live load of occupants. This allowance may be somewhat less than the usual allowance of 1¼cwt. for the ordinary floors of dwellings per square foot of their area, as the probability of its containing a moving crowd would be very remote. Probably a ½cwt. to ¾cwt. per square foot would be a sufficient allowance to make for this purpose to include ordinary furniture, but would be exclusive of the weight of the flooring joists, plastered ceiling, etc. The weight of a full water-tank of 2ft. 7in. height of galvanized iron with fittings would be about 2¼cwt. to 2½cwt. per square foot of bottom area, the weight of water being 10lb. per imperial gallon, and there being about 6¼ gallons in a cubic foot. The weight of single ceiling joists of dry fir to sustain attic floor, together with flooring boards, may range from 9lb. to 12lb. per superficial foot; lath and plaster ceiling two coats 9lb., three coats 10lb. per foot super; ceiling joists for counter ceiling adds 2¼lb. to 2½lb. per square foot. The weight of roof trusses varies with span and pitch, the spacing apart, and the kinds of materials used in the construction. Approximate weights may be obtained by reducing it to the horizontal projection of the floor area covered by the roof, and then multiply a unit area as a square foot by the weight of the horizontal projection of the portion of the roof supported by the truss—i.e., the bay or the space between the centres of two adjacent trusses. On this basis an average may be arrived at for the ordinary pitch of one-quarter span, using a king-post truss, say, up to 35ft. span, and for larger spans a queen-post truss. The weight of a dry fir truss complete, including tie-beam, for 20ft. span will be 1¼lb. per square foot of floor area covered by the half of its bay on each side of it; 30ft. span, 1 9-10lb.; 40 ft. span, 2½lb.; 50ft. span, 2 3-5lb.; 60ft. span, 3½lb.; 70ft. span, 3 4-5lb.; 80ft. span, 4½lb.; 90ft. span, 4 4-5lb.; 100ft. span, 5⅓lb.; for each additional 10ft. of span add ½lb. For intermediate spans interpolate the corresponding proportion of the difference for the spans adjacent to it.

The purlins, ridge board, and ridge roll add 2lb. to 2½lb. per square foot of floor area covered by roof. Common rafters add about 3⅓lb. to 3 2-5lb. per foot super of floor area covered; sheating of 1in. thick boards of fir, spruce, or pine (white) 3lb. to 3½lb. per square foot of roof surface; Georgia pine, oak, ash, 5lb. per square foot. The weight of the external covering adds as follows: lead, 6cwt. to 8 cwt. per square of 100 square feet; slating laid with 3in. lap, including nails, but not battens or iron laths, for doubles 13in. by 9in. and ladies 16in. by 8 in., 8¼lb. per square foot of roof surface; countesses, 20in. by 10in., 8lb.; duchesses, 24in. by 12in., 8½lb.; tiles, 11in. by 7in., plain, with 3in. lap, mortar pointing, including laths and absorbed damp, 18lb. per square foot; pantiles, 13½in. by 9½in., including same as plain tiles, 12lb.; Italian, ridge, and furrow tiles, including pointing and damp, 14lb.; slate battens, 3½in. by 1in., for doubles, 2lb.; for countesses, 1¼lb.; zinc roofing, 14 to 16 zinc gauge, 1½lb. to 1¾lb.; galvanised iron, corrugated, 16 wire gauge, 3½lb.; 18 wire gauge, 2½lb.; 20 wire gauge, 2lb.; sheet iron, 16 wire gauge, 2½lb.; 20 wire gauge, 1½lb.; thatch, including battens, 6½lb. From the foregoing data, approximate weights of roofs can be estimated, making allowance for increase of length of rafters over the span for other roof pitches; thus if the value of the half span be 1, then the length of the rafter for quarter pitch is 1·12, for one-third span pitch 1·2, for three-sevenths span pitch 1·32, for half-span pitch 1.414. These weights of the roof, together with the weight of all appendages, all act in a vertical direction. An allowance for the weight of accumulation of snow is also made, say 5lb. per square foot of floor area covered by roof is considered sufficient for this country. In America this same allowance is made for localities such as St. Louis, Richmond, Louisville (Ky.) in north latitude about 37½deg. to 38deg.; 10lb. is allowed in Baltimore, Cincinnati, and Indianapolis; 15lb. is allowed in Philadelphia, Pittsburg, and Wheeling; 20lb. in New York City, Cleveland, Chicago, Des Moines; 25lb. in Boston, Albany, Buffalo, Milwaukee, St. Paul; 30lb. in Northern New England and New York States, Michigan and Minnesota. Some writers have suggested that the allowance for the stress produced on a roof normally to the inclination of its pitch by wind pressure of the maximum force used in practice, would sufficiently cover the allowance for snow, as before such a maximum wind force could take effect upon the windward side of the roof all the snow would have been blown off it, and hence the allowance for snow according to this suggestion need not be made, except for very cold climates. The suggestion, however, could not apply to flat roofs, "well roofs," and such as are completely sheltered by solid parapets or otherwise protected from the force of the wind. It may be observed that in cold countries the snow is generally frozen into solid ice on sides of roofs to which the sun rays have direct access. The direct stresses on the roof, therefore are distinguished as (1) the permanent loads, estimated on the basis just detailed; (2) the accidental loads (a) as snow, and (b) wind pressure. These pressures should all be determined separately, and then any combination of them which produces the greatest sum of stresses affecting any member of the truss should the stress value to be adopted in estimating the strength and stiffness of each member thereby affected. The same principle will likewise apply to the stresses produced on the resisting planes of all joints and joint articulated connections with the truss members.

The weight of the roofing material, or the external covering of slates, tiles, etc., as well as that of the snow and the wind pressure direct or reversed, is sustained by the common rafters in the first instance. It is by them transmitted to the purlins which support the common rafters at intermediate points, their ends being supported respectively by the ridge piece or purlin, and by the wall plate. It is usual to divide the external and structural loads, acting upon the common rafters, equally between the points of support, so that each intermediate point shall have double that at each end. Such a distribution, however, assumes that the common rafters

are cut through over each purlin, so that they would thus act as separate beams. But as the common rafters are not thus usually cut through over the purlins, but are continuous, having proportional cantilever reactions over each intermediate support up to the points of contraflexure, the position of the points of contraflexure or their distance from the supporting intermediate purlins, and the value of the bending moments and moments of flexure, depends on the depth of the rafter or continuous beam, the distribution of the load, elasticity of the material, etc. The formulæ for thus obtaining the distribution of the load over the various purlins are complicated and need not be given here, as they have been calculated for the usual scantlings of common rafters of fir. The proportions of the distribution here to follow are based on a continuous uniform cross-section of straight rafter, supporting a uniformly distributed load. The points of support are equidistant from one another, and their bearing surfaces all in the same straight line. The loads for the two halves of the spans continuous over several supporting purlins are alike; it is therefore only necessary to give the lowest or eave half of the continuous rafter supports. When the number of spans is odd the number of supports is even, and there is no centre support. But when the number of spans is even and the number of supports odd, the centre support is the turning point of the values of the purlin loads for both halves. Thus when there are two spans and three supports the wall plate and the ridge pieces each bears ⅜ of the load upon their respective spans, and the purlin bears 10-8 of a similar load. When there are three spans and four supports, the eave and ridge piece each bear 4-10 of the single-span load, and the two intermediate purlins each bear 11-10 of the same load. Similarly, when there are four spans and five supports, the wall plate and ridge bear 11-28 of single-span load, the second and fourth supports bear each 32-28, and the third or middle purlin bears 26-28 of the single-span load. For five spans with six supports, the wall plate and the ridge each bears 15-38, the first and fourth purlins 43-38 each, the second and third purlins each 37-38 of load.

The practical difference that this ratio of distribution of the loads over the rafters, and consequently over the purlins, will affect roofs of large span and having the trusses set a considerable distance apart—say, upwards of 12ft. or 14ft. In such cases the scantlings of the purlins would require to be proportioned for the increased ratio of load. In ordinary roof timbering the scantlings of the purlins would all be alike, but in such case they should have sufficient strength for the maximum apportionment of load. Taking as an example the case of two spans and three supports, the difference in the load on the purlin between treating the rafters as two separate beams and one continuous beam is that in the former the purlin would only bear half of the entire load on the rafter, whereas as a continuous beam it bears five-eighths of the entire load. The excess of load as a continuous beam imposed upon the purlin is thus one-eighth of the entire rafter load for the whole span of the purlin. If the span of the purlin be 14ft. between the spacing of the trusses and that the purlin was placed 8ft. from the wall plate, the load area of roofing supported by it would be 112 square feet. Then suppose the permanent load on the purlin, including its own weight, all uniformly distributed, were 26lb. per foot super for plain tiles, the total would be 2,912lb., or, say, 3,000lb. in round numbers. The excess of one-eighth of the entire load or one-quarter of the above, half-rafter load would be 750lb., and if the wind load were, say, three-fourths of the above say 563lb., the total load would be 1,313lb. This proportionate excess in such a case as assumed, would be a sufficiently large excess to require a special computation of the strength of the purlin so as to be safe against bending under it on the occurrence of a storm of wind.—The Contract Journal.

VENTILATING AND WARMING STABLES.

Before considering the ventilation, it will be well to see what is a proper and sufficient area of floor space for stables and loose boxes, and also the cubic space that should be given for each horse.

In practice the sizes of stalls and loose boxes vary according to the space at command, without in most cases any reference to sanitary considerations, but a good standard size for a stall is 6 ft. wide by 9 ft. long, from the wall to outside of stall post; if they are wider than 6 feet the horse has too much room and can turn around in the stall, while if longer than 9 feet the horse is dwarfed in appearance.

The gangway at the end of the stalls should not be less than 6 feet wide in a stable with stalls on one side only.

The size of loose boxes is not affected in the same manner, and very good dimensions for a loose box are 12 feet long by 12 feet wide; but it should not, unless under very exceptional circumstances, be less than 10 feet by 9 feet, and the gangway should be 6 feet wide, whether the boxes are along one only or both sides of the stable, and the doors should open outwards.

Taking the above as standard sizes we get the floor areas as under:

For a stable with stalls on one side, 90 square feet per horse.

For a stable with stalls on both sides, 81 square feet per horse.

For loose boxes on one side only, 216 square feet per horse.

For loose boxes on both sides, 180 square feet per horse.

The cubic space to be allowed to each horse varies according to different authorities from 900 to 1,600 cubic feet for an ordinary size animal. Hutton gives 1,560 cubic feet as necessary. We should say that it should not be less than 1,500 cubic feet, which is one and a half times that laid down by the best authorities as requisite for a healthy sleeping apartment for a human being; and we may, we think, safely assume that this proportion will not be excessive for an animal like a horse, considering the exhalations that must arise from soiled litter, etc.

This capacity, taken with the floor areas already given, gives a height of 16 feet for a stall stable with one row of stalls, 20 feet for a stable with two rows, and about 9 feet for loose boxes.

It will be at once recognised that while the floor area actually given does not in most cases vary very much from our standard, the cubic capacity is seldom given except in some high class hunting and other stables in the country, and never in London, where it is very uncommon to find a stall stable having more than 1,000 cubic feet per horse, and that insufficiently ventilated.

The following examples are from stables in existence.

Unfortunately the cubic space is not so complete as we should wish it. We have not had time to supplement it, but those examples we have taken will be recognised as good ones.

	Floor area	Cubic space per horse.
Gifford Hall Stables, stall	120	1680
" " loose boxes	216	3020
Wretham Hall, loose boxes	185	
Frogmall, Kent, stalls	134	
Moreton Hall, stalls	126	
" " loose boxes	216	
Cowesfield House, stalls	120	1080
" " loose boxes	240	3780
Easton Park, Suffolk, stalls	105	
" " " loose boxes	150	
Lock Inch Castle, stalls	130	
" " loose boxes,	195 to 250	
Claremont House, stalls	130	
Copse Hill Hunting Stables, stalls	130	
Ditto loose boxes	186	
Berkswell Hall, stalls	128	
" " loose boxes	190	
Havering atte Bowe, stalls	147	
" " " loose stalls	120	
Private Stables at Brighton, stalls	95	
Ditto loose boxes	104	
Private Stables in London, stalls	84	798
Ditto loose boxes	100	950

From these examples it will be seen that, even in superior town stables, the cubic capacity is actually below that required for the human being.

In the country stables, the floor spaces are in nearly all cases equal to or more than our standard, while the cubic space is considerably more in the case of loose boxes, showing that the amounts we give as standards are generally recognized as being necessary for a really good stable.

In the following remarks we shall therefore assume the cubic space to be dealt with as 1,500 cubic feet per horse, and the average height of the stable as 15 feet; and with this explanation our readers will be able to correct the quantities hereafter given to suit other capacities.

The next step is to decide what quantity of fresh air is required to be admitted in summer and winter; but as in summer the extra quantity required can be easily supplied by opening the windows, which must be provided for lighting (for it must not be forgotten that light is as necessary as air to maintain a healthy state of body, whether in man or horse) it will be sufficient to consider what ventilation is required in the winter only.

Dr. Parkes, in his well-known work on Hygiene, says we should allow 6 cubic feet of fresh air per minute for a man; M. Peclet and Mr. Hood give from 3½ to 5 cubic feet of fresh air per minute, as the minimum quantity that should under ordinary circumstances be allowed for a human being in the winter to maintain the wholesomeness and purity of the apartment; and it seems reasonable to assume that a horse would require at least half as much again, or say, 7½ cubic feet per minute in the winter, and double that in the summer, and a further allowance must be made on account of the exhalations from soiled litter, etc.

The size of the inlet ventilators should, according to Dr. Parkes, be 24 square inches per man, and the Commissioners on improving the sanitary condition of Barracks, etc., laid down 1 square inch for every 60 cubic feet capacity, which, on 1,500 cubic feet gives an area of 25 square inches—we, have, however, considered that a horse requires 1½ times the space, and consequently the air, that a man wants, and therefore the area for each horse should be 37 square inches, which, allowing the maximum velocity that can be permitted without causing a draught, viz., 3 feet per second, gives an admission of 46 cubic feet per minute, equivalent to changing the whole air of the stable twice in each hour.

This quantity of air will be delivered when there is a difference of 10 deg. between the outside and inside temperatures.

There must, however, not only be inlet ventilators for the admission of fresh air, but outlet ventilators for the escape of the vitiated air, and, quoting Mr. Hood, "it is advisable to make the aggregate area of the openings that admit the fresh air larger than the aggregate openings for the efflux of the vitiated air. This becomes necessary notwithstanding the increase of volume which takes place in the heated and vitiated air."

If the opposite course be adopted, and the outlets be larger than the inlets, then a counter-current takes place, and the cold air descends through the outlet tubes unless prevented by some special means, and by making the inlet of large area the velocity of the incoming current is reduced, and unpleasant draughts avoided.

It is also expedient to divide the entering current as much as possible, for by so doing the dangerous effects of cold draughts are prevented when the entering current is colder than the air of the room; and when it is hotter, it prevents the air from rising too rapidly towards the ceiling and therefore distributes it more equally through the apartment.

Provided the aggregate openings for the admission of cold air be not less in size than those for the emission of the heated air, the quantity of air which enters depends less upon the size or number of the openings which admit the fresh air, than upon the size of those by which the vitiated air is carried off.

We have now arrived at this result, that for each horse we require 37 square inches of inlet valve area, while the outlet area must be less; say 20 or 30 square inches per horse.

Outlet valves should either be taken into chimney flues or into special shafts made for the purpose, and carried up as high as possible above the ceiling of the stable. The valves themselves should be placed close up to the ceiling.

Everyone with a knowledge of stable matters knows that there is more or less stagnation of air at the head of a stall, closed in as it is on three sides, and with the manger plate projecting some 15 to 18 inches into the stall at a height of about three feet above the floor, thus forming a kind of open box; also in a range of loose boxes where the only air that gets into the bottom of the boxes is what finds its way under the doors, which are often kept an inch or two off the floor for the purpose. Attempts to remedy this have been made by keeping the sills of stalls and loose boxes an inch or two off the floor, with the result that a space was left in which horses were liable to catch their feet, and which it was difficult to get under to clean.

The new arrangement consists of a new form of sill, of girder shape, having the webb connecting the upper and lower flanges perforated with holes. The bottom flange is made flat to rest on the floor, with caulkings going into the floor to secure it laterally. The top flange is made with a groove to take the woodwork, which is thus kept well above the floor and away from all damp. At the head of the stall or loose box an iron plate takes the place of part of the woodwork, and below the level of the manger plate, this is perforated in a similar manner to the sill, so that the air can circulate freely from stall to stall, or box to box, throughout the length of the stable. The section of the sill is such that there are no corners in which dust can accumulate, and it can readily be swept or washed clean by a broom, and there are no projections or corners against which a horse can injure himself.

We have given the areas of inlets and outlets for, what we consider sufficient ventilation for the winter, but this must be supplemented in summer, as already mentioned, by windows. There is no doubt that a stable, to be healthy, should also be light, and where possible overhead skylights should be given; but in the majority of cases this is impossible, and we should then advocate glazed hopper or swing windows above each stall or loose box, and where there is only one row of stalls or boxes, ordinary sliding windows on the gangway side opening top and bottom with their sills not less than 5 feet above the floor.

The actual area of windows required varies, according to different authors, from 1 to 10 square feet for each cubic feet of space. It may therefore be assumed that it should not be less than fifteen square feet for each horse, more being given according as the light is obstructed by other buildings, etc., in close proximity.

This article has now extended to such a length that we have small space for any remarks on warming. It must therefore suffice to say that 5 square feet of hot water pipe heating surface per 1,000 cubic feet of space, or 7½ square feet per horse, should be sufficient; and hot water coils should if possible be placed in the space beneath a window and so protected that there may be no projections against which a horse could injure himself when passing.

MARBLE IN INTERIOR WORK.

Now, when we come to interior work, a new field is open to us. We are not bound by influences such as those that have been under our consideration. What we have to consider primarily is strength of material for its purpose; secondly, its adapability; thirdly, and generally to the client the most important, its appearance when finished. With all due respect to your president's opinions, I, if I followed my own inclinations, should give marble the premier place as an internal material. Doubtless a number would say that marble is out of the question for general purposes, its cost is so great; but marble does not itself ask for treatment such as you give to stone. Work executed in marble can and should be finished so as not to have any appearance of grimness or even of dinginess.

Marble should not be looked upon as a constructional, but rather as a decorative material; and, looking at its use from a monetary point of view, I would quote Mr. W. Brindley's paper before the Royal Institute of British Architects some two or three years back, where he tell us that "at St. Sophia 2,000 feet super of delightful decoration of a durable character was cut out of a single block of Cipollina marble, the whole opened out and making a continuous pattern." The small slab we have here is of the same material, and is a scale pattern of the pavement in St. Mark's, Venice. Then, again, to adapt marble to concave or convex surfaces, I would ask you to visit the church lately erected by Dr. Freshfield at Lower Kingswood. You will find that we have followed out the scheme of the Byzantines, viz., forming the convex face of the apse with a series of narrow slabs opened out chevron fashion, thus producing a curtain-like appearance, which has a very pleasing effect. To save such work as this in fact, all slab work from having the appearance we find in some churches, and what your president rightly deprecates, several things have to be considered. For instance, if the walls are built of mortar, the sand of which is Thames sand, so-called; but if that sand comes from the mouth of the Thames, that constitutes sea sand. Consequently you will get that dampness and efflorescence that is usual with that kind of mortar; the walls being "eased" with marble, the salt naturally finds its way through. Marble should never be fixed solidly to the wall, but left hollow, and also with a joint here and there left open to allow for the condensation that invariably takes place. The work should be well cramped to the wall with copper cramps. The best of plaster should be used in fixing, and I have no hesitation in saying that if slab work is fixed under these conditions, and with a care in selecting suitable marbles, you will get satisfactory work, as shown by the slab work at the vestibule of the Athenæum Club, National Gallery, and other places I could mention. These buildings were all in a proper state to receive marble. Then, again, as to keeping the work clean after it is fixed. All that is required is proper attention with dry dusters. Marble work should never be washed down as you wash tiles. The dust that clings to anything damp, if rubbed constantly on the polished surface, is literally ground into the face of the marble. This applies more especially to the light marble. But if a perfectly dry dusting is given to your work I venture to say that the result will be satisfactory. These may seem very ordinary remarks and may weary my hearers, but they are of great importance if you want satisfactory results.

The mason is a methodical man. If he works a moulding—say a cornice, for instance, or a string mould—he would proceed by applying his section to chamfers and then working his chamfers through. Now, in designing your moulding this should be taken into consideration, as moulding drawn to suit the method of working seems to me to be only right, and in support of this I would ask you to examine the old specimens that are here, and also the diagram.

Work drawn on these lines, especially in marble, lessens the cost of labor considerably, the mason being able to get at it much better than if at the outset you upset his method of working. You will also observe that marble moulding drawn on these lines can be got out of these slabs and made out with a core of stone, thus giving you in effect solid cornices, etc. In drawing your sections for marble it is very essential that you should have a knowledge of the material and its capabilities of receiving mouldings. The composition of the various kinds varies to such an extent that a moulding that could be worked in one marble would be quite out of the question in another. For instance, take a chimney piece in statuary or Pavonazza, and then one in the Cipollina or Rouge Etrusque. What could be produced in the former materials would be quite out of the question in the latter. Speaking generally, the rich colored marbles do not ask for an elaborate treatment in the way of mouldings; in fact, the different colors, lines and markings of the material are very apt to upset the arrangement of mouldings unless they are treated in a broad manner. The use of machinery has considerably reduced the cost of marble work in England during the past few years, and also the time taken in production. The use of marble by the architects during this revival, may I call it, has been very great, and I believe will be greater in the future, when its adaptabilities are more widely and better known.

[1] From a paper read by Mr. Hervey Flint before the Architectural Association, London.

HAMILTON ART SCHOOL.

The annual meeting of the above school was held on the 14th of September, Rev. Dr. Lyle occupying the chair in the absence of the president. The report of the principal, Mr. Ireland, stated that during the year 54 students were enrolled, and that the school was making satisfactory progress. The receipts of the year were shown by the secretary's report to be $3,522.01, which, with a balance of $102.15 from last year, made a total of $3,624.16. The expenditures amounted to $3,450.54.

The following were appointed the committee on examinations for 1896-7: John Knox, Thos. Beasley, F. W. Watkins, J. T. Barnard, G. H. Bisby, W. D. Long, J. J. Mason, A. O'Heir, F. B. Greening, J. Pottinger, Dr. Gaviller.

The government medals and certificates and the local prizes were given out. The following awards were announced:

Architectural perspective—No prize given for lack of funds; Herbert H. New, 1st hon. men.; no 2nd and 3rd; hon. mentions given to increase value of 1st.

Architectural design Harold H. Mundy, winner; H. G. Batton, 1st hon. ment.; Herbert G. Mason 2nd, and P. Stewart 3rd.

Drawing from the antique, full figure—Walter R. Duff, winner; Mabel S. Ireland, 1st hon. men.; Jessie Kellar 2nd, K. Saunders 3rd.

Pen and wash drawing for illustrating—Marion E. Mattice, winner; C. Locke, 1st hon. men.; A. N. Browne 2nd.

Building construction Andrew P. Stewart, winner; Ralph Mason, 1st hon. men.

Design for tiles and glass No prize given for lack of funds; Ben. Kilvert, 1st hon. men.; no 2nd and 3rd hon. mentions given to increase value of 1st.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.

PROCEEDINGS OF THE RECENT ANNUAL CONVENTION AT MONTREAL.

THE Province of Quebec Association of Architects met in annual session on Thursday the 8th inst., at 10 a.m., in their rooms, New York Life Building, Montreal, the President, Mr. A. C. Hutchison, in the chair. Among those present were: Messrs. A. C. Hutchison, President; A. T. Taylor, 1st Vice President; J. F. Peachy, 2nd Vice President; Jos. Venne, Secretary; Jos. Perrault, Treasurer; A. H. Lapierre, Theodore Daoust, Robert Findlay, J. Z. Resther, Councillors; H. Ç. Nelson, W. E. Doran, A. G. Fowler, Maurice Perrault, J. R. Gardiner, J. W. Hopkins, Simon Lesage, E. Mann, E. Maxwell, G. A. Monette, P. A. R. Labelle, James Nelson, Alphonse Raza, L. Z. Gauthier and James Wright of Montreal; Chs. Baillargé, J. F. Peachy, F. X. Berlinguet and G. E. Tanguay, of Quebec.

Letters of regret were read from different members.

In a brief address the President called the convention to order.

Reports of the Treasurer and Auditors were received and adopted, also the report of the Council which was as follows:

REPORT OF COUNCIL.

The fifth annual meeting of the Association held in the city of Quebec in October, 1895, was well attended, and the Council takes this opportunity of acknowledging the generous reception tendered the Council and members from Montreal who attended that meeting by their confreres in Quebec, and to testify to the interest taken in the Association by the members resident in Quebec.

Many items of interest to the Association were discussed at that meeting, and the following were referred to the Council for its consideration:

First: The holding of an exhibition of architectural drawings on the occasion of the annual meeting in 1896.

Second: The preparation of a schedule of professional charges for the use of members.

Third: The preparation of conditions to be observed in competition for public buildings.

Fourth: To prepare a standard form of contract.

The Council regrets that owing to the difficulty in obtaining a quorum of its members many meetings could not be held, and it was unable to accomplish all the work allotted to it; they, however, present this report of the work they were able to accomplish.

EXHIBITION. Early in the summer it was decided to give effect to the resolution of the Association to hold an exhibition of architectural drawings, and it was resolved that the scope of the exhibition should be widened so as to include modern artistic work applicable to architecture, and a loan collection of antiques.

The preparation for this exhibition has, during the last three months, occupied most of the time of the Council and of members of the Association whom they associated with them to assist in making the necessary arrangements.

As the funds of the Association could not be drawn upon to meet the expense of such an exhibition a number of the members have subscribed to a guarantee fund which it is hoped will defray the cost.

The Council leave to the members to judge, when the exhibition is opened this evening, as to whether it is a success or not, bearing in mind that most of the drawings are the individual work of the members, and if the exhibition is successful the Association as a whole will benefit by it.

The Council would gratefully acknowledge the help extended to it by the Art Association of Montreal in promoting and carrying out the exhibition, and in placing their galleries at our disposal. Without the assistance thus rendered it would have been impossible for your Council to have carried out such an undertaking.

SCHEDULE OF CHARGES. The schedule of professional charges has been prepared and is now in the hands of the printer and copies will be mailed to members in a few days. The procuring of the signatures caused considerable delay in its preparation.

COMPETITION FOR PUBLIC BUILDINGS.—The preparation of conditions to govern members in competition for public buildings received but slight consideration owing to the difficulty in obtaining meetings of the Council and to the political events during the year which prevented securing the co-operation of public officials.

ASSOCIATION COMPETITIONS.—At the request of the Editor of the CANADIAN ARCHITECT AND BUILDER the Council named a standing committee consisting of the president, vice-presidents and secretary during their term of office to whom all competitions under the auspices of the Association or of the CANADIAN ARCHITECT AND BUILDER will be submitted.

STUDENTS' ASSOCIATION.—The students connected with the Association formed themselves into an organization for the advancement of their interests and for mutual improvement in their studies. With a view to promote these objects the Council gave the use of the rooms and library free, only stipulating that the cost of lighting and necessary attendance should be paid, and that students availing themselves of these privileges should register their names in conformity with the by-laws.

For some unexplained reason the meetings have not been continued, and the privileges granted have not been taken advantage of.

STANDARD FORM OF CONTRACT.—Owing to the difficulty before referred to of holding meetings, because of the non-attendance of members of Council, the preparation of a standard form of contract could not be undertaken, and this matter will have to be referred to the new Council.

AMENDMENTS OF CHARTER.—The members of the Association resident in Quebec presented a number of amendments which they wished to have made in the charter, but after careful consideration the Council deemed it best not to approach the Legislature for the present.

AUGE BILL.—When this bill was before the last session of the Legislative Assembly, the Council, as on former occasions, asked for its repeal. Although their request was not granted, such modifications were made as to do away with the most objectionable clauses.

ART COMMITTEE. A committee appointed by the Council to confer with the corporation of Montreal and request the appointment of a Standing Art Committee had interviews with the mayor. The mayor expressed himself in favor of the appointment of such a committee, and promised to bring the matter before the Council and aldermen, but so far no definite action has been taken, and the matter still remains in obeyance.

BUILDING BY-LAWS. The committee regret that the corporation of Montreal have not yet given consideration nor effect to the building by-laws prepared by the committee appointed by it, and on which so much time and labor was expended. It is hoped that the corporation may at an early date adopt the by-laws as submitted to them.

EXAMINATIONS FOR REGISTRATION.—At the semi-annual examinations held in Quebec in the month of January, three candidates presented themselves for examination for registration—all of whom, namely: Messrs. J. E. Payette, J. Ferget Despatie and P. A. R. Labelle succeeded in passing in the subjects prescribed in the by-laws, and received their diplomas. At the same examinations one candidate, M. P. Leveque, presented himself for matriculation examination, and was successful in passing.

At the semi-annual examinations in July only one candidate entered for matriculation, M. Rene Frechette. As he was from Quebec, the examiners did not think it worth while for him to undertake the journey when there were no other candidates. It was therefore proposed that the candidate present himself for examination next January, and that if he succeeded in passing his time of study would date from July last.

The Council have to report the following case which has been presented to them and in which they could not grant the request made without violating the act of incorporation and by-laws. The case is as follows: A student passed the matriculation examinations and then entered the office of an architect who is not registered. Having completed his term of probation, he wishes to enter for final examination and, if successful, be registered.

As this case presents difficulties that the Council did not feel warranted in overcoming without violating our charter, it is referred to this meeting.

LIBRARY. No additions have been made to the library during the year, except "Les Grands Prix d'Architecture," engraved and published by A. L. F. Vandoyer and L. P. Baltard, Paris, 1834, donated by M. J. Venne, and the proceedings of the American Institute of Architects. The periodicals subscribed for by the Association have been bound and placed on the shelves.

MONTHLY DINNERS AND PAPERS.—During the winter months the dinners and reading of papers instituted in former years were maintained, but, owing to the apathy of members, they were not so successful as they should be.

The following papers were prepared for these monthly meetings: "Ancient Rome," with lime light illustrations, by Alex. C. Hutchison; "Old Colonial Architecture," by Robert Findlay; "Truth in Architecture," by W. E. Doran; "Evolution of the Plan in Building," by Jos. Venne.

MONT ST. LOUIS INSTITUTE.—The directors of the Mont St. Louis Institute have made the request that in view of the course of instruction in architecture given to their pupils, that the time required for service in an architect's office after they have been admitted to study shall be three instead of four years. As the granting of this request would be in conflict with the act of incorporation and by-laws, the question is referred to this meeting.

REGISTER.—The names of several members have been removed from the register for non-compliance with the by-laws respecting the payment of subscription, and the Council regret to record the decease of M. J. B. Resther, who took an active interest in the formation of the Association, and was ever ready to assist in furthering its objects. A special meeting was called on the day of his funeral and a suitable minute of condolence made, and a copy sent to the family. A wreath of flowers was also sent and placed upon the coffin.

ATTENDANCE AT MEETINGS.—The following is a record of the attendance of members at meetings of council: A. Ç. Hutchison, president, 20; A. T. Taylor, 17; J. Venne, 20; J. Perrault, 14; R. Findlay, 14; J. B. Resther, 6; A. H. Lapierre, 7; T. Daoust, 4. Messrs. J. F. Peachy, 2nd vice president, C. Baillargé and G. E. Tanguay, residing in Quebec, are not inscribed in this register.

There were, besides the requested meetings of Council, a number of meetings of committees appointed by the Council to assist in carrying out the work of the Association, more particularly in connection with the exhibits.

The Council would place on record its appreciation of the assistance thus rendered.

THE PRESS.—The thanks of the Association are tendered to the Press for interest and notice of its proceedings.

JOS. VENNE, Secretary.

The report submitted by the Treasurer, Mr. Jos. Perrault, was of a very satisfactory character, showing a strong balance to the credit of the Association in bank.

The reports of the Council and the Treasurer having been adopted, the election of officers was proceeded with, and resulted as follows, the scrutineers being Messrs. G. E. Tanguay, of Quebec, and H. C. Nelson, of Montreal: President, A. T. Taylor, Montreal; first Vice-President, J. F. Peachy, Quebec; second Vice-President, A. Raza, Montreal; Secretary, Jos. Venne, Montreal; Treasurer, E. Maxwell, Montreal; Council, A. C. Hutchison, Jas. Nelson, J. Wright, R. Findlay, Montreal, Chas. Baillargé and F. X. Berlinguet of Quebec.

Auditors: Messrs. G. E. Tanguay and H. C. Nelson.

The most important feature took place in the forenoon session on the tariff of charges. There were lively discussions. M. Berlinguet, of Quebec, said that the tariff at present in the hands of the Lieut. Governor should not be sanctioned, being in some respects too high and in others too low. M. Baillargé called the attention of the meeting to the fact that an architect was not allowed to testify in his own case, as the other professional men could do.

It was proposed by Mr. A. Raza, seconded by Mr. Perrault, that this important question should be referred to the new Council for consideration at a special meeting, and that a report thereon be presented as soon as possible.

The idea of having a Dominion Association of Architects was favorably received, and has been referred to the same committee. Mr. C. Baillargé, of Quebec, and M. Perrault referred to the advantages of such an association.

The request of the authorities of the Mount St. Louis Institute was taken into consideration, but no immediate conclusion was reached.

The retiring president then introduced his successor, Mr. A. T. Taylor, who thanked the members of the Association for the honor conferred upon him, and said that he hoped that they would help him to make the Association a flourishing one.

In the afternoon the invited guests and Quebec members were driven through the city and to Laval University and the Diosesan College of Theology, which buildings they thoroughly inspected. The party then went around the mountain and greatly enjoyed the scenery.

THE EXHIBITION.

The second exhibition held under the auspices of the Province of Quebec Association of Architects in the galleries of the Art Association, Phillips Square, was a pronounced success in every respect, and augurs well for similar undertakings in the future.

Although the drawings were inferior in number to those of the exhibition of two years ago, there was a noticeable advance in point of excellence which ought to amply reward the promoters for their labor, and be appreciated by the profession as a whole, and the public at large.

If the architectural drawings occupied less space than in the former exhibition, together with the exhibits of the Arts and Crafts Department, the entire space occupied this year was far greater, two galleries being entirely taken up, and part of a third. The Arts and Crafts Department was a most valuable addition and is destined to bring to light many an ignored artist in the line of decorative sculpture, painting, iron work, and other allied arts closely connected to architecture.

The exhibition was inaugurated in the evening by a delightful conversazione, which was attended by a large and select society. Sweet music was discoursed and refreshments served in the large class room adjoining the new gallery.

The following is a list of the drawings exhibited in alphabetical order by authors:

Archibald, John S., Montreal, 1, Church of St. Bertrand and Street in Lisle, France; Barnes, R. Percy, Montreal, 2, Church at Philipsburgh, 3, "Claremont," Pointe Claire, 4, "Glynn Hedd," Lachine; Bigelow, Henry Forbes, Boston, U. S., 5, Perspective of St. Mark's School, Southborough, Mass., 6, Perspective of the Grand Stand for Readville Trotting Park, U. S. A., 7, Perspective of a Block of Shops at Gilbertsville, New York, U. S. A.; Brown, McVicar & Heriot, Montreal, 8, Summer Hotel at Chambly, 9, Sketch for Three Houses, 10, Interior of Hall, 11, Apartment House, Peel street, 12, Sketch for an Apartment House, 13, Residence of C. Davidson, 14, Residence of A. J. Inglis, Westmount; Cox & Amos, Montreal, 15, a Block of Seven Cottages at Westmount, 16, Designs for Additions to the College of St. Laurent, 17, Design for Altar and Reredos Church at Rougemont, P. Q., 18, Block of Stores, St. Catharine Street, 19, House at Westmount, 20, Residence at Kensington; Daoust, Theodore, Montreal, 124, Perspective of College at St. Henry, 125, Front Elevation of House; Department of Public Works, Ottawa, 21, Interior of Library of Parliament, 22, Perspective of Drill Hall, Halifax, 23 to 31, Public Buildings at Winnipeg, Victoria, Berlin, Port Hope, Clifton, Hull, Bathurst, New-

castle and Amherst respectively; Dufort, Cajetan, Montreal, 32, Detail of a Courtyard, 33, Chickering Hall, 34, House of Geo. Willis, Chicago, 35, Columbia College, 36, Swampscott, 37, a Summer Residence; Findlay, Robert, Montreal, 38, Residence of W. M. Knowles, 39, Residence of Dr. D. F. Gurd, 40, Residence of R. Findlay, 41, Residence of J. L. Morris, 42, Residence of W. R. Miller, 43, Residence of J. Allan, 44, Residence of J. S. Sheffield; Finley, S. Arnold, Montreal, 45, Sketch of Old House at Laval, France, 46, Sketch of Old English House, 47, Sketch for Shooting Box, 48, Rambling Sketches; Fuller, Thomas, Ottawa, 40, Design for Capitol at Albany, 50, Design for Church, 51, Ground Plan of Public Building at Victoria; Gardiner, J. Rawson, Montreal, 52, Design for Board of Trade Building, 53, Two Cottages, Green ave., 54, Lindfield Church, England, 55, a Lakeside Cottage, 56, a Bit in Westminster Abbey; Hutchison, Alex C., Montreal, 57, Two Villas at Westmount, 58, Y.W.C.A. Association Building, 59, Proposed Melville Church, Westmount, 60, Design for Hospital, 61, Design for Presbyterian Church, Point St. Charles; Kilham, Walter H., Boston, U.S., 62, Group of French Towers, 63, Italian Doorways, 64, Study for Custom House; Lindsay, H., Montreal, 65, Perspective of Hall in Residence of Mrs. J. Levy Messrs. J. & H. C. Nelson, architects; MacVicar, D. Norman, Montreal, 66, Sketches in Reims, France, 67, "Town Tower," Oxford; Maginnis, Charles D., Boston, U. S., 68, Massachusetts State House, Boston, 69, Sketches in Rouen, France; Mann, Eric, Montreal, 70, a Street in Old Edinburgh, 71, Residence for M. S. Foley; Maxwell, Edward, Montreal, 72, Board of Trade Building, Montreal Shepley, Rutan & Coolidge, architects 73, Westmount Primary School, 74, Bell Telephone Building, Montreal, 75, Bell Telephone Building at Winnipeg, 76, R. J. Tooke's Building, 77, Banking Room in Bell Telephone Building, Montreal, 78, Residences, Montreal, 79, Cottages, 80, a Study, 81, Chapel at Avignon, France, 82, St. Ouen, Rouen, France, 83, Foreign Sketches, 84, Tower of University Chapel Palo Alto, California, 85, Country Residence, 86, Bridge, Back Bay, Fens, Boston, 87, Study for a Residence; Miller, J. Melville, Montreal, 88, a Mountain Hotel; Mitchell, C. Alexander, Montreal, 89, Sketch of Old House, Grey street, 90, Sketch of Old Porch in Normandy, France; Nelson, J. & H. C., Montreal, 91, Perspective of House for Mrs. J. Levy; Nelson, H. C., Montreal, 126, The Old Savage Farmhouse, Sherbrooke Street, 127, The La Salle House, Lower Lachine Road; Patterson, C. B., Montreal, 92, Residence Baltimore, 93, Sketch for Church; Payette, Eugene, Montreal, 94, A City Residence, Submitted in Final Examination to the P. Q. A. A.; Perrin, W. M., Montreal, 95, Perspective of Frame House, 96, Perspective of Stone House, 97, Perspective of Chapel, 98, Rendering from Photograph, 99, Cottage in Sepia; Raza, Alphonse, Montreal, 100, Residence of O. Faucher, 101, Club House, Lake Chapleau, 102, Residence for A. Armot; Rodden, R. M., Montreal, 103, 104, 105, Plans For Public Library; Saxe, C. J., Montreal, 106 and 107, City Mansion, 108, Colonial Residence, 109, County Residence, 110, Summer Residence, 111, Shakespeare's House, Stratford-on-Avon, 112, Sketch; Taylor, Andrew T., F. R. I. B. A., Montreal, 113, Diocesan Theological College, Montreal, 114, Bank of Montreal, Seigneurs Street Branch, 115, Additions to Art Gallery, Montreal, 116, Leaves From a Sketch Book; Venne, Joseph, Montreal, 117 and 118, Perspective Views of a Church, 119, Competition Design for Church at St. Jerome; Winslow and Wetherell, Boston, U. S., 120, House at Lake Massahesic, N. H., 120 and 123, Houses at Brookline, 122, Business Premises for Shreve, Crump & Son, Boston.

Mr. Andrew T. Taylor, F. R. I. B. A., contributed water color perspectives of buildings of actual interest, such as the Diocesan Theological College just completed, which undoubtedly ranks amongst the best of the very interesting buildings erected by this talented architect. The drawing representing this building although well rendered in color, conveys but a faint idea of the beauty of the original. In plan three sides of a quadrangle overlook University street, the principal side carrying a graceful tower in its axis while opposite an elaborate gothic gateway separates the court from the street. It is thoroughly English in character and we feel that Mr. Taylor was well at home in designing this building and succeeded without effort in making it what he intended it to be. A water color perspective of the new Art Gallery shows also with advantage, together with five or six water colors of Italian towers which could well form part of a worthy pendant to "Sir Christopher Wren's Towers and Spires," which Mr. Taylor had published in London by Botsford when practising in the Commercial Metropolis.

Mr. Joseph Venne exhibits two perspective drawings of a proposed church, one of the interior rendered in color, and one of the exterior rendered in ink. The porch is remarkably well proportioned and detailed, as is also the choir, which is well studied. The interior is of a semi-classical character and very rich and elaborate in design. An elevation of a competitive design for a church at St. Jerome also exhibited by Mr. Venne has well proportioned and arranged doorways.

Mr. A. C. Hutchison had two perspectives of villa residences erected at Westmount, designed in the American style and very well rendered in ink, together with other remarkable drawings, amongst which is the Y. W. C. Ass'n. building designed in very good taste.

Messrs. J. & H. C. Nelson's house for Mrs. J. Levy shown by two drawings rendered in ink is an agreeable and unpretentious design with a well arranged and detailed staircase.

Messrs. Findlay and Maxwell exhibited a large number of drawings the former having mostly pen and ink drawings, while the latter exhibited mostly water colors, which were much admired.

Nearly all of the drawings sent in by American architects are also worthy of praise, and the Arts and Crafts Department had also very interesting and numerous exhibits which would also deserve some attention but the space being so very limited in this number, little can be said for the present.

We cannot, however, close without mentioning Mr. Philippe Hebert's beautiful group entitled "Le Rapt" representing an Indian holding a girl on his shoulder with his left hand and a threatening knife in his right hand.

Mr. Page exhibits some iron chandeliers and grilles refined in design and of a finish rarely met with in daily practice.

Briefly the success and high degree of excellence which the present exhibition has attained is a guarantee that regular and periodical exhibitions of this character will be held in the future, which institution would do a good deal for the advancement of architecture, and a more intelligent appreciation of that useful art by the masses.

ENTRANCE TO VICAR'S CLOSE, WELLS CATHEDRAL. SKETCHED BY MR. FRANK S. BAKER, A. R. I. B. A.

RESIDENCE OF MR. COLUMBUS GREENE, ST. GEORGE STREET, TORONTO. BEAUMONT JARVIS, ARCHITECT.

The materials employed in the construction of this house are plum-colored hard burned brick and light grey stone. The trimmings are painted in bronze green.

YOUNG MEN'S CHRISTIAN ASSOCIATION BUILDING, LONDON, ONT. MOORE & HENRY, ARCHITECTS.

The building is 110 feet by 100 feet, 4 stories high, built of stone and brick, with slate roof and plate glass windows.

The basement contains the bowling alleys, swimming tank, locker and dressing rooms, shower, tub and needle baths, toilet rooms, heating apparatus, etc. The first floor contains an octagonal reception hall, secretary's offices, boys' rooms, reading room, large parlor, lecture hall and gymnasium, together with cloak rooms and toilet rooms. The auditorium is also on the first floor with a separate entrance having direct access to the street. The second floor contains the board room, ladies' parlor, large entertainment hall, kitchen, upper part of gymnasium, with running track and visitors' gallery and the gallery of the auditorium, also the quarters of the London Etomological Society. The third floor contains class rooms, public and private offices, cloak rooms, etc.

The whole building is thoroughly lighted and ventilated, having wide corridors running through to connect the different apartments, wide staircases, and is to be heated by low-pressure steam with thorough ventilation. The contracts call for the building to be completed in October, 1896.

DESCRIPTION OF THE FIRST PRIZE DESIGN FOR THE CANTILEVER BRIDGE, OVER THE RIVER ST. LAWRENCE. BY EDWARD S. SHAW, C. E., BOSTON, MASS., U. S. A.

It is proposed to build this bridge over the River St. Lawrence, about two miles below the Victoria bridge, with a long cantilever span of 1250 feet, over the main ship channel, and at a clear height, throughout the central portion of this span, of 150 feet above the summer level of the river. The approach viaduct on the Montreal side will commence near the corner of Delorimier avenue and St. Catherine street, thence upon a curve and over the shore span of the cantilever bridge to the main pier of the long span, situated on the edge of the wharf near Belle Rive Park. Thence the long span crosses the main channel to the other main pier and beyond to an anchorage pier, both upon Ile Ronde, a small island in the river just below St. Helen's Island. From Ile Ronde the wider but shallower portion of the river is crossed by a bridge and viaduct on a descending grade to the Longueuil shore.

In the advertisement for competitive designs issued by the Montreal Bridge Company, certain requirements were given, the most important of which were the length of and clear height above water of the channel span, and the nature of the traffic over the bridge to be provided for, this latter being stated to require two railway tracks, two tracks for electric street cars, a highway for ordinary vehicles and two footways. Other minor stipulations were made, and a blue print outline of a design was sent out to applicants, but it was stated that these were not intended to hamper designers, original designs being invited.

The accompanying illustrations show, as one of the main features of this design, two massive stone piers, situated upon the margins of the main ship channel on the Montreal wharf and on Ile Ronde, each 110 feet by 30 feet in plan, at the top, and rising to a height of 60 feet above the summer level of the river, these piers being surmounted by the balanced arches, of compound curvature, of the superstructure. In continuation of the ascending lines of the stone pier, a steel pier or column of massive proportions towers to the height of 230 feet above the sub-pier, or fully 300 feet from summer water to the lanterns or turrets upon the summit.

From the tops of these towers the upper cords descend in approximate catenary curves, suggesting the curves of the main cables of a suspension bridge, to the junction with the free span of 350 feet which connects the two cantilever arms, these arms being each 450 feet in length.

The long span of 1250 feet and its two flanking spans of 600 feet each are divided by the four main trusses into three longitudinal ways, the middle of which, 26 feet in clear width, carries the double track steam railway, while the two side passages, each 21½ feet in clear width, suffice for the highway and street car tracks. Bracketed out from the outer trusses are the sidewalks, 6 feet in clear width each.

Throughout the middle portion of the long span, for a distance of 650 feet, the elevations of the several ways are practically the same, this portion of the bridge being built with a camber or slight upward curve, increasing the headroom at the centre to 153 feet. Commencing at points on this span, distant 300 feet from each of the main piers, the approach grades (2 per cent. and 4 per cent. respectively), of the railway and highway commence, the greater grade of the highway, street car tracks and sidewalks sufficing to bring down these portions of the floor enough to pass under the railway tracks upon the spans adjacent to the anchor piers, and to continue under, and descend with the same grade as the railway tracks, upon the approaches.

The main trusses or longitudinal supporting frames of the cantilever and flanking spans, as well as the trusses of the approaches are built vertical or plumb, instead of in planes inclined outwardly or "battering," as in the Forth bridge and also in many high viaducts and long span arch bridges. Where a bridge supports only a single or double track railway or narrow or medium width highway it is necessary to spread the base of the supporting trusses, arches or towers, to secure sufficient stability to prevent the structure from being overturned by excessive wind pressure, but in this structure on account of the great breadth of the bridge required for the several ways, this breadth being 80 feet measured between centres of outer trusses, it is apparent that it may not be necessary to slope or batter the trusses in order to obtain the requisite base to render the structure stable against the most severe winds of ordinary or periodical and frequent occurrence, and in this design the trusses have been placed in vertical planes, with advantages of simplicity of design and cost of construction. In the main piers steel buttresses are built out at right angles to the plane of the trusses, increasing the width of the superstructure base, and heavy steel anchors are provided, extending down almost to the base of the masonry sub-piers near their

ends, to guard against the possible effect of winds of extraordinary violence.

The lower chords of the flanking spans of the cantilever bridge, and of the longer spans of the south approach, are curved down to the stone piers of the substructure, both to diminish the height of, and quantity of masonry in the substructure and to improve the appearance of these portions of the design.

In the south approach there are 15 spans ranging from 300 feet down to 160 feet, the lengths and depths of these spans being varied in approximate proportion to the height of grade above the water. From the last span shown on the southerly side, the highway and electric car tracks are carried upon a solid embankment, with sloping rock-built sides, the railway being upon an elevated structure over the middle of the highway.

The approach viaduct, upon the curve on the Montreal side, is a structure simulating an arch viaduct, with full centre round arched trusses, having a sufficient centre depth to be self-supporting and to exert no horizontal thrust upon the substructure, under vertical loads.

It is proposed to use the European style of all riveted connections throughout, no eye-bars or pin connections being used, excepting possibly in anchorages. While the pin connected method of bridge construction is preferred by the majority of bridge engineers in the United States, short span bridges excepted, the riveted method is almost exclusively used in Europe, and the immense Forth bridge, the largest rigid bridge in the world, stands as a conspicuous precedent for the employment of this system of construction for bridges of exceptional magnitude.

The bridge has been designed to carry a heavy train of locomotives and cars upon both of the railway tracks with a proper allowance for the travel upon the highways and sidewalks, and for wind pressures, and with working strains ranging from $\frac{1}{6}$ to $\frac{1}{3}$ of the breaking strength of the material, according to position and duty.

It is proposed to use mild open hearth steel throughout, having an ultimate tensile strength from 60,000 to 72,000 pounds per square inch, and with restrictions as to the amount of phosphorus and sulphur, the impurities which, if contained in excess, are most prejudicial to the good quality of steel, and its ability to resist impact, or sudden blows or shocks.

The estimated weight of structural steel is 37,000 tons of 2,000 pounds, and the estimated cost of the superstructure is $3,514,000.

EDWD. S. SHAW, C. E., Boston, Mass.

A WORD OF CAUTION.

THE enthusiastic Canadian student of architecture who may be planning a visit to the Paris Exhibition of 1900, will do well to remember that in some of the Provincial towns a person attempting to make a sketch in the streets is liable to find himself arrested and held by the police as the emissary of a foreign nation which is preparing for the invasion and conquest of the republic. The absurdity of such official interference appears to have dawned upon the mind of the Prefect of Police of Paris, for an order was recently issued that artists and photographers are not to be interfered with unless by reason of them crowds of people congregate and impede the traffic in the streets.

PRISMATIC GLASS.

ONE of the latest and probably most important improvements in building material is the prismatic glass for transoms and sidewalks, introduced by the Prismatic Glass Company a few months ago. This window glass is made in small squares, which are put together with lead or other material to suit size of windows or transoms. The inner surface of the glass is covered by horizontal ridges or half prisms. These half prisms are so constructed that when a light ray which falls naturally at an angle of about 45 degrees passes through this glass it becomes refracted or bent upwards and is carried out horizontally into the interior of a room instead of falling to the ground or floor at the natural angle. This is a very simple contrivance, but the result is wonderful. In one jewelry store in Toronto, where the glass has been introduced, before using the prismatic glass, upwards of 40 and on cloudy days 80 incandescent lights were required to give sufficient light in the interior. Since using prismatic glass the proprietors of the store say that they have not required any artificial light except on very dark days, and that they have saved from $40 to $80 per month in their artificial light bills. The same result has been experienced by three of the largest departmental stores in Toronto who are using the glass. Architects and owners who have used prismatic glass are emphatic in their praise of its result.

The sidewalk lights work on a somewhat different principle. The rear surface of each prism acts as an independent reflector and an ingenious but simple arrangement is made so as to provide for the slant of a sidewalk, and still allow these reflectors to throw light into the interior of a basement without being diverted or tilted up, which is the result in most pendant or prismatic sidewalk lights.

Although only on the market for a few months in Canada, both prismatic window glass and the sidewalk lights have met with large sales and nearly all the important mercantile and commercial buildings erected in the principal cities in Canada have been fitted out with this glass.

The use of this glass does away with the necessity of light wells and sky lights, which always serve as fire traps and use up valuable space.

The City of Venice has announced its intention of holding a second International Art Exhibition, to contain pictures, sculptures, etchings, and drawings, from April 22 to October 31, 1897. Prizes for the best works to the amount of not less than 40,000 lire will be awarded by an international jury of artists. The Municipality of Venice will grant three prizes of 1,500, 1,000 and 500 lire respectively for the best critical essays on the exhibition, published during the first month after the opening. Artists must give notice of their intention to exhibit not later than January 1.—The Building News.

As it is often difficult to obtain any information concerning the inside height of a church or other building, Korber mentions in the "Deutsche Techniker Zeitung" that he has found toy balloons very useful for this purpose. The string must, of course, be very light. A straw smeared with a little glue placed at the top of the balloon helps to keep it in position for a few moments. It may, unfortunately, prove quite as difficult to procure a toy balloon good enough for the purpose, as to hunt up papers and drawings containing the desired information. But Korber is not wrong, when he says that somebody might prepare balloons specially for this purpose.

STUDENTS' DEPARTMENT.

THE PRACTICAL SIDE OF TRAVELLING.

UNDER this heading Mr. A. Needham Wilson gives the following hints in A. A. Notes to architectural students abroad in search of knowledge:

It seems to be a somewhat invidious task to lay down any general rules of procedure for foreign sketching tours, the necessities and circumstances differ so widely according to the line of route of the country traversed that nothing more than personal experiences can be given, and the neophyte must glean what he can from the variety offered him. It has to be borne in mind that the student is about to study architecture produced under a different aspect, under a different climate, and governed by atmospheric conditions totally distinct from those of our own country, and though it may be necessary to lay down some fixed route, or fix upon a list of notable buildings, there must be a temptation to search for untrodden ground. Some notion—further than a mere broadening of ideas of future usefulness, must be in the mind of the student, to be gathered from the material he will collect during his tour, and naturally he will pick this up as fancy leads him. Therefore I venture to think the idea of working from some centre is a useful one. More luggage can then be carried, as the bulk can then be left at your base, and bare necessities only taken afield. Sometimes it will be found practicable to live in apartments, or en pension, and then a few luxuries will be found most welcome. To Mr. Bolton's suggestions as to outfit, I have little to add, as I consider them excellent. There are one or two points, however, to which attention might be given. Slow drying water colors will be found very necessary in extremely hot weather, and personally I found two folding campstools indispensable. They are light and easy to carry, and for plotting dimensions on the spot, form a handy trestle for the drawing-board by placing one above the other. For certain work a bamboo rod or reed, 10 or 15 feet long, will be found very useful in measuring to otherwise inaccessible points. These are generally easily procured, and need not be carried from place to place, and, above all, take a sketching umbrella.

Personally speaking, I cannot say I have found such extreme difficulty with regard to credit notes as Mr. Bolton has, as the centres from which I worked had duly accredited agents, and I certainly never lost by the exchange. It must be understood that I write of certain parts of the south of France, with which I am more intimately acquainted. Living there is extremely cheap, providing that you shun the grand hotels.

My companion and I lived luxuriously at one small hotel for forty francs a week for the two, "en pension."

Mr. Bolton appears to stand in great awe of concierge and sacristan, and speaks contemptuously of introductions. I certainly agree with him that the credentials furnished by the Royal Institute are of little use, but the best credentials I had were cards furnished by a government architect to whom I had an introduction. It proved an "open sesame" to me to everything. A case in point. I had seen through an archway a court, in a certain city. I applied for permission to sketch. The owner, a noble, was absent. The concierge said it would be all right. We accordingly commenced work. A scion of the noble house turned us ignominiously into the street. We produced our credentials our passport, our Institute card, our Academy bone, our A. A. ticket, our letter. We implored; we threatened to write to the Times; but the stony-hearted youth (about fifteen) saw us off the premises. We went to our protector and returned armed with a note. Instantly the place was at our feet. "Everything is at Monsieur's service." "Would Monsieur like a table and a chair?" M. le Comte regaled us with Malaga; we had the run of the place; we sketched old furniture. Madame la Comtesse apologized, and we felt that we were Britons again. Armed with those cards we penetrated places that no Briton had ever seen or heard of. We walked unscathed amid police and "gendarmerie," and even sketched the ancient tower of the "Mairie" at Avignon from a window of the gendarmerie itself. I never bothered with sacristans and concierges. I went invariably to the head authority and procured proper permission. In this I never failed, and as a result was never interfered with. Of course, in travelling from the beaten track, I repeatedly had to seek permission to sketch where no sacristans or guardians existed, and then I found our powerful friend's influence most marked. The permission of the priest or other in charge never failed to secure me from any annoyance. I certainly found it saved instead of wasted time.

Do not let a student go abroad with a fixed idea that the fact of his being an Englishman is sufficient to secure him the entree everywhere, without proper permission. Such conduct causes more trouble and gives us a worse character than many imagine; and certainly if you differ in creed with that of the church in which you are working, do not offend the susceptibilities of worshippers and authorities by conduct that you would not be guilty of in your own land or church of your own creed. Even if no stipulation to such effect is made, it is expected that you will cease work during Divine Service. Remember that as you act, so it will be better or worse for those who may follow in your footsteps, and an indifference to others' feelings may cause your successors endless trouble. As a case in point, I may mention that the priest in charge of the grand church of S. Trophime, at Arles, hesitated for some time before giving permission on the grounds that other students had persisted in sketching during service and on Sundays. At St. Gillies, Gard, the cure spoke in terms of strong indignation of the conduct of certain English, who, forsooth, because they were Protestants, seemed to think it unnecessary to respect the feelings of those who differed from them. It may be annoying to break off in the middle of your work, but a little arrangement will obviate this. Is it a large church with a fine west elevation? sketch outside till the sun drives you in. When service commences, go into the cloisters.

Both clergy and sacristans will consider you if you consider them, and, speaking personally, neither in England or abroad have I ever found the consent given grudgingly by the clergy. Though you may have a right to be in a church, it does not follow that you have a right to sketch.

To turn to another matter; do not be content with a superficial examination of a town. The tide of modern improvements may only have covered up much that is worth the seeking. It is there if you will look for it. Nimes, with few exceptions, is a city of plain streets, and yet a mass of rich Renaissance work was found hidden behind the plain exteriors, much of it sketched

for the first time by an Englishman. In suburbs and outskirts, in outlying towns and villages, I have rarely failed to find something worth a walk. Surely half the charm of a lengthy tour is to discover the unknown.

In conclusion, I would venture to urge the advisability of measuring and plotting to scale on the spot, whenever practicable, whilst everything is at hand and before your eye, and when there is no possibility of the vivid impression fading from your memory.

I would only add to Mr. Bolton's admirable remarks on sketching the advice to draw firmly and strongly.

MANUFACTURES AND MATERIALS

CEMENT WORKS IN GERMANY.

There are, according to Kuhlow, some 63 cement works in the whole of Germany. The Rhine is the principal centre of this manufacture, but in the neighborhood of Hamburg there are three or four in operation for the production of the article. The annual production of Germany amounts to nearly 11,000,000 barrels, giving employment to some 1,800 hands, whose annual earnings amount to some £698,780. The largest customers for this article in Europe are Russia and Norway, and of transatlantic countries, the United States, Brazil, Chili and Venezuela. The exportation to Great Britain and British possessions is comparatively small. The following table gives approximately the quantity and the value exported to European and other countries :

Country.	Cwts.	£
Norway	58,500	6,700
Russia	34,353	2,900
United States	1,380,872	168,000
Brazil	446,340	40,200
Chili	131,000	13,000
Venezuela	103,000	9,800

NATIVE BUILDING MATERIALS OF THE CANADIAN NORTHWEST.

A Canadian contributor to the Engineering and Mining Journal of New York gives the following information with regard to the native materials available for building purposes in Manitoba and the Northwest Territories :

The artice that comes next in importance in the way of building materials to lumber is lime, which is used largely in plastering and mortar, and where good clean gravel is readily obtained, may, and in the future probably will, be utilized largely in the construction of concrete buildings. Limestone is found in drift to a greater or less extent through Manitoba and the territories. It is found in situ to an unlimited extent near the mouth of Dauphin River, extending for some miles both east and west of the same. There are also large outcrops on Lakes Manitoba and Winnipegoosis, and the Rocky Mountains in this region may be said to be wholly composed of this material. The writer in preparing this paper does not desire to create the impression that he has endeavored to report all the points at which outcrops of such materials are found ; but is merely mentioning localities where such have come under his own personal observation.

Where limestone is being mentioned as found in situ, good quarries of the rock for building material are readily obtained ; in fact, in very many points are already opened and fairly well developed, and before leaving this branch of the subject it might be well to direct your attention to the probability of very extensive quarries of limestone being developed at the narrows of Lake Manitoba, the rock there lending itself very readily to a smooth finish at a low cost, and it is also alleged that the nature of the formation is such that blocks of large size can be easily quarried.

Both granite and limestone drift rocks may be found nearly everywhere to a greater or lesser extent throughout Manitoba and the Northwest, and, where they are large enough, they can generally be split into any desired shape or size, and even where comparatively small masons can construct buildings not alone substantial, but also ornamental. While on this subject it may be of interest to mention a series of huge granitic rocks which have been deposited, no doubt through the influence of ice, along the foothills of the Rocky Mountains. To convey an idea of the size of some of these, it may be mentioned that one particular boulder located on Section 21, Township 20, Range 1, west of the fifth meridian, shows above ground a bulk of 50 feet in length, 30 feet in width and about 25 feet in height. How large a portion of it is hidden from sight below the ground has never been determined.

Those who have had an opportunity of seeing the bridge piers erected by the Canadian Pacific Railway over the Winnipeg River here have no doubt been struck with the splendid appearance of these specimens of Aberdeen granite, of which they are composed. This material is obtained in the immediate vicinity, and the probabilities are that there is a very large field of this stone which can be had in blocks of any dimension, and there can be no doubt it is susceptible of as high and fine a polish as its original namesake, the "Aberdeen granite," of Scotland, and it will probably in the future take a prominent part in the construction of any works where such material is required.

There is a large outcrop of sandstone in Lake Winnipeg, which is pronounced to be first-class. There are also some sandstones to be found in the vicinity of Turtle Mountain, the qualities of which, so far as endurance is concerned, would appear to be all that could be desired ; but owing to its color and texture it is doubtful whether it will ever find a market outside of the local consumption, for which, however, it is liable to become very valuable. An outcrop of sandstone may also be seen on the Assiniboine River in the neighborhood of Indian Ford and some stone has been brought to Winnipeg from this point ; but owing to its cost it was not a successful financial venture. It may be useful for local purposes, but probably not beyond that. When the Cypress Hills are reached there are a considerable number of sandstone outcrops and very extensive beds are crosscut in places by the South Saskatchewan, the Red Deer, the North Saskatchewan, the Bow, the Belly, the St. Mary's, the waterton, and the Old Man's Rivers ; but the finest quality of sandstone is undoubtedly found along the foothills of the Rocky Mountains and the supply there is practically inexhaustible, enough to rebuild all the cities in the world as they exist at the present time. It would seem a great pity that with so much stone, in the country our hard-earned cash should be sent across the line to our neighbors for the purchase of stone, as both quality and color is in favor of the domestic article. One is not rash in prophesying that the extensive use of red sandstone will prove anything but pleasing and soothing to the eye if carried to excess.

Vast deposits of this rock are met with in the Rocky Mountains and can be obtained in any size blocks that is required. This material is very well fitted for bridge piers, in fact any structure which is liable to be exposed to the action of water, combined with low temperature.

Where the Canadian Pacific Railway crosses the backbone of the continent there is a large outcrop of slate which gives every promise of becoming a valuable article of good quality as soon as there is demand enough to warrant capital going to the outlay of developing. There is a deposit situated on Kicking Horse River, near its mouth, which was mined or quarried to some extent a few years ago. Some was shipped to the coast, but the action of the moist climate there was too severe for it and disintegration set in. It is, however, more than probable that the same slate, if used in Manitoba or the Northwest Territories, would prove a very good roofing material and withstand the influence of the atmosphere as well as most other roofing slates.

In the Rocky Mountains, along the line of the Canadian Pacific Railway there are to be found very large bulks of quartz carrying copper stains, which are capable of receiving a high polish, and are of a very beautiful color, resembling marble in finish, and would no doubt prove useful and ornamental for the manufacture of table tops, mantels, etc.

The notice announcing to members the first meeting of the Chicago Sketch Club, following vacation, reads as follows : "Members will come prepared to discuss fish stories, summer girls, century runs and similar topics."

Mr. C. E. Sintum, the Canadian Commercial Agent in Norway, reports an increasing trade between that country and the Dominion, and incidentally mentions that he recently gave a considerable order for steam radiators to a Toronto firm.

THE BUILDER

[THIS DEPARTMENT IS DESIGNED TO FURNISH INFORMATION SUITED TO THE REQUIREMENTS OF THE BUILDING TRADES. READERS ARE INVITED TO ASSIST IN MAKING IT AS HELPFUL AS POSSIBLE BY CONTRIBUTING OF THEIR EXPERIENCE, AND BY ASKING FOR PARTICULAR INFORMATION WHICH THEY MAY AT ANY TIME REQUIRE.]

Storm Windows.

It is now time in this northern climate to prepare for the winter, and abundant orders will be placed in the sash and door factories for storm sashes and doors. In order to make storm sashes effective they should be made to cover the whole front of the window frame, and held in place by screws which should pass through the sash stile and grip the casing. This, of couse, cannot be done in a majority of cases, particularly if there are venetian blinds hung to the windows, as it would entail the necessity of taking off the blind trimmings in the fall and putting them on again in the spring, with all the chances of having them mislaid or lost. When the blind trimmings prevent the screwing on of the storm sashes on the outside of the casings, they should be fitted snugly between the casings, and if the sashes are thicker than the casings, which is often the case, the inside of the sash should be rebated over the blind stop, sufficient to admit of the sash dropping into the frame far enough to let the stile be flush on the outside. When this is the case, the storm sashes may be held in place simply by the use of the common Japanned cast iron button which may be obtained at any hardware store for about ten cents a dozen. By making use of these buttons, the labor of placing and removing the storm sashes is made about as light as it is possible to make it, especially if two hardwood dowels be set in the top-rail of the sash, and corresponding holes be made in the head casing to receive the dowels ; then, two buttons, one on each side of the frame, will answer for each sash. These buttons should be fixed low down the frame, near the sill, and should be tight enough to prevent any movement of the sash by the action of the wind, and thus prevent the buttons from turning and allowing the sash to get free and fall out of place.

Storm sashes should never be less than 1⅜" in thickness ; indeed it would be much better if they were made 1¾" thick, as they meet with a good deal of bad usage and wear and tear, in being put up and taken down so often. It is a mistake, also, to make storm sashes with large lights in imitation of the sashes they cover. In the frequent removals, in and out of the window frames, the glass is liable to get broken and more particularly is this the case if the panes are large, and the cost of replacing a large pane is an item worthy of consideration. Small panes cost less if they get broken, and they are not so liable to be broken, owing to their being protected with the mullions and muntins. These mullions and muntins also strengthen the frame and fit it better for the hard usage it has to endure. It goes without saying, that storm sashes of all sorts should be well painted. In the best style of work the sashes get two coats of good paint, composed of white lead and linseed oil, before being glazed ; they should also be fitted in place and numbered before being painted, and the edges, top and bottom, as well as sides, should be painted. All the glass should be well bedded in good putty and well held down with a goodly supply of glaziers' zinc points. Much depends on having the glazing well done, for, as storm sashes are more exposed to severe weather than other sashes, special care should be taken when the glass is put in the sash, in order to make it firm and secure. Some painters mix a fair proportion of white lead, moist or dry, as may be needed, with the putty to make it adhere firmly to both glass and wood. This method has its faults, inasmuch as should a pane of glass break, it is next to impossible to break out the putty to make room for the new glass, as the lead and putty becomes as hard as stone.

Storm Doors.

Storm doors, like storm sashes, should be made somewhat stronger than the ordinary door, and to this end, when the doors are framed and panelled, they should have all the muntins mortised into the rails sufficiently deep to admit of tenons, not less than 2" long, which, by the way, should fit snug in the mortise, and white lead should be used as a holder instead of glue. It will be well also if the plough grooves are painted with white lead before the panels are slipped in, as, by doing so, the life of the door will be prolonged from 15 to 25 per cent. The rails should be well fastened into the stiles, and the tenons should be well painted before being driven into the mortises. It is always best to employ three butts in hanging a storm door, the third butt, besides assisting to hold the door, will do much towards preventing it from twisting or warping, a condition that too often occurs in storm doors. All the butts, of course, should have loose joints, as this will enable one to take off the door without taking off the wings of the butts. A very important matter in connection with a storm door is the lock and its furniture. This should be of the very best quality, and should be heavier than the lock on the inner door, while its furniture should be of the same style and finish. In all cases it should be a mortise lock, and should be attached to the door in the most substantial manner. The keeper should extend round the jamb a trifle if possible, in order to protect the jamb or casing from being shattered if the door should be dashed by the wind against it, while the bolt may be shot out, which is sometimes likely to happen. When storm doors are taken down in the spring, they

should be laid carefully away in such a manner as to prevent them from warping, bending or twisting, and put where no water can get at them. The keys should be tied with fine wire to the knobs, and the pins belonging to the loose butts should be fastened to the butts also by a short strand of fine wire. These simple precautions may be the means of preventing much inconvenience and annoyance when it becomes time to again put the doors in service. All of the foregoing relates more particularly to panelled storm doors, but the same hints and suggestions to a large extent, are applicable to the ordinary batten door, with the exception, perhaps, of the locks, for where a batten door is used for a storm door, a thumb latch is generally employed in place of a lock, and where this is the case, it is the better way to get the best thumb latch for the purpose obtainable.

Chimney Building.

THERE is no part of a house that requires more care and thought in its construction than the chimney if good results are desired. Yet there is no part in which so little skill, and what may be termed building science, is usually displayed, as in the construction of chimneys. Nothing contributes to the health and comfort of a household in a greater degree than a good chimney, one that will do its duty without having to be forced or doctored. To obtain the best results possible, so far as known at present, the following suggestions should be considered and adopted where the conditions will admit: On no account put a chimney on a flimsy foundation. If, as is sometimes the case, it is necessary to build a chimney from a stand, it should be seen that the plank or timber forming the uprights of the stand, rest on a good solid foundation, and not on the flooring or joists as is frequently done. Many buildings have been destroyed by fire originating between the ceiling joists and roof, because of defective foundations, which have settled, and the brickwork of the chimney shaft having been held in between the joists or roof timbers, has separated at the junction, thus leaving an opening from the flue to the woodwork, which, being dry, was easily ignited by the first spark or flame that found its way through the break. A chimney shaft should never be built so that ledges of brickwork rest on either studding in the walls, joists or roof timbers. This is frequently done, but it is a bad and a dangerous practice. When built from the ground the foundations should be deep enough in the ground to be below the action of frost, and if built so as to form part of an outside or cross wall, it should be well tied or bonded with the stonework of such wall.

When it can be done the flue should be as nearly perpendicular and straight as it is possible to make it, and should be smooth inside, without angles, corners, jogs or contractions, and at no point in its entire length should wood of any kind be near it. Wherever the shaft passes through a floor or a roof, the floor or roof should be "trimmed" around the brickwork, and a space of an inch left clear between the wood and the brickwork; this space can easily be made water-tight in the roof, by proper flashing. If the building should be a frame or a "baloon" one, the brickwork should be kept at least four inches from the outside of the wall. The flue should be "parged" or plastered with a mortar composed of one part fresh cow dung and three parts of ordinary cow dung well mixed and applied the usual way. This mixture should be made as required and used before it has time to set and become hard. A flue so treated will present a smooth glassy surface, hard as a rock, and soot will not accumulate on its sides, while the draft will be much improved. The draft may be further improved by increasing the area of the flue about an inch every ten feet in its height. This increase of area must not be made suddenly or by a jog, but gradually all the way up, from bottom to top. Under no consideration whatever should joists or timbers of any sort, or for any purposes, rest on or in the brickwork of a chimney, for they simply make hidden incendiaries that may some day lead to the destruction of the whole building. An ordinary flue intended for service in a dwelling house where wood or soft coal is used for fuel should contain an area of about 125 square inches, and not less than 96 square inches. If hard coal is used as fuel, the latter number of square inches of area will answer very well. Each fire-place or stove-pipe should have a separate flue, for, if a number of stove-pipes enter the same flue the draft is sure to be defective and troublesome. Wherever it may be necessary to pierce a flue to suit a stove-pipe, the flue should be enlarged at least one-fourth in order to enable it to perform the extra work imposed on it by the addition of another fire.

If a fire-place is connected with the chimney, its hearth should be built independent of the floor timbers, and should rest on brick or stone work and should be filled up nearly level with the floor with concrete, on which hearth tiles or neat cement should be laid to the proper height. In constructing the fire-place care should be taken to contract the throat and keep it well forward, so as to be directly over the fire. In making the contraction, experience has shown that the best system is to start to draw in the brickwork or contract the throat, just at the haunches of the jambs, and make the contraction from both sides, on an angle of 45 degrees, continuing on this angle until the desired flue area is reached, then continue the flue as described in the foregoing. The chimney breast should be made to measure in the room exactly 4 ft. 11 in., so that when a half inch of mortar is applied to both sides by the plasterer, the breast will measure just five feet, which is the regulation size for the width of mantels. The plastering, of course, is rendered on the bare brick work. If a pressed brick mantel is intended to form the fire-place it may vary somewhat from the measurement given, the dimensions, however, may be obtained from the firm from whom the pressed bricks for mantels are to be purchased.

While bricks on edge are permissible for dividing flues from one another, the outside wall of the chimney ought never to be less than six or eight inches thick. A six inch wall may be constructed by laying the outer course of bricks on their flats, and the inner course on their edges and when the courses are all on one plane on top, lay a course of "headers" chopped off to six inches in length, putting the broken end inside the flue as it will act as a bond for the parging. For an 8" wall the bricks may be laid as headers and stretchers every alternate course. The best hard faced bricks will be used for that portion of the shaft that will be exposed to the weather, and good sound bricks should be used throughout the whole work. It is advisable to place a soot drainer at the lower end of every flue so that the chimney may be cleared from soot whenever necessary. The foregoing remarks refer exclusively to chimneys built altogether of bricks, but are in a great measure applicable to chimneys built of stone or of adobe. Generally when a chimney is built of stone it is either lined up with bricks or vitrified drain tiles, the latter, when of sufficient area, make the very best flue and are reputed to be the safest as they never gather soot. Adobe chimneys, many of which are found in the remote settlements and on the prairies, should be plastered inside with mortar made as described earlier, and the whole should be left until perfectly dry before any fire is allowed to approach it. Abobes or "dobys" as the westerner calls them, are simply mud bricks, neither more nor less. In dry climates like New Mexico and Arizona and other parts of the southwest they are much used in building, and many of the old forts, mud forts, were built of "dobys," and they have bravely stood the weather for many a long year. In the absence of bricks the Canadian settler often makes use of the "doby" to build the chimney of his log cabin, but he generally mixes cut stone with the mud, and instead of calling his "brick" a "doby" he calls it a "cat." We have never been able to discover the reason why the latter designation was given to the mud brick, but suspect it comes by some round-about way from the Quebec French. Can any of our readers solve the puzzle?

METHODS OF ESTIMATING FOR PAINTERS.

THE use of a reliable system of measurement, which can be laid before the patron, and charging by the piece, or foot or yard, rather than by the "lump," is worthy of general adoption.

In many places the "square" of 100 superficial feet is used. On some work a man can paint six "squares" a day, while on other work he may be able to paint only three squares in the same time. The charges are made to suit these variations, and is preferred by many to the more elaborate, though really more reliable method of applying different prices to different sorts of work. The claim made for the system is that such fixed rules as these, though involving occasional hardships, will obviate the disputes that are likely to arise from differences in the judgments of divers measurers. This system is worthy of noting here, and it is as follows:—

EXTERIOR PAINTING.

1. All plain surfaces are to be measured by their length, multiplied by their breadth. No deduction to be made for ordinary doors and windows. Nor is any addition to be made for scaffolding, staging, etc.

2. On irregular surfaces, such as mouldings, panels, etc., the tape line must follow the contour of the surface, and into depressions, quirks, etc., wherever the brush has properly been.

3. On frame buildings, the thickness of the edges of clapboards, shingles, siding, etc., to be added to the length of the surface.

4. In all cases where the terminal edge is cut in, six inches is to be added to such cutting for each foot in length.

5. In windows and glazed work, when the amount of cutting-in exceeds the surface measurement, the additional cutting-in is to be added to the surface measurement.

6. In shutters, blinds, and other finish containing movable or fixed slats, such slats are to be measured. In trellis work, also, double the measurement.

7. In ornamental work, such as cornices with dentils, medallions, brackets, etc., the parts of the work so ornamented are to be measured as double work and added to the moulded work already measured, as provided in Rule 2.

8. In balustrades, balconies, stairwork having balusters, the opening in which the balusters occurs is to be measured as equal to one-third of the surface for measurement.

9. In ornamental iron cresting, grille work, etc., the surfaces are to be measured and the amount multiplied by three.

10. Picket fences, gates, etc., are to have one-half of their surface measurement added thereto.

INTERIOR PAINTING.

11. Rules for exterior painting apply to interior work as far as practicable.

12. Wood-finishing subject to same rules as painting.

13. In all cases of wall painting the height is to be measured from tip to base or wainscot to the ceiling, and no openings of less than 3 ft. wide are to be deducted. Where the opening is from 3 ft. to 6 ft. wide, one-half of its contents are to be deducted, but one-sixth in width is to be added for each side of the openings, its entire length.

14. In calcimining or wall tinting, the walls and ceilings treated are to be measured over all, and no deductions for openings to be made. The same rule to apply to white-washing.

15. In all cases of wall painting or calcimining where plaster cornices are painted or tinted, the girth of the cornice to be measured double and added to the wall surface. Where ornament is painted in such cornices, etc., the provisions of Rule 7 are to be observed.

16. All striped work and stencilled border or frieze work must be measured by the lineal foot.

17. No carved work, plaster centres and ornamentation, foliated capital of columns, statuary, etc., are subject to measurement, but are to be charged for by the piece.

18. Painting finished in more than one color, measurements as for plain painting. The extra cost to be in the price charged for the work, but all striping in gold or colors to be measured by the lineal foot.

19. In measuring beaded ceiling or wainscot, or other work in which sunken beads are found, for each bead not more than 1½ in. wide, add 1 in. to the length of surface measured.

20. In all floors, hardwood or otherwise, all wainscot, base, surbase, picture moulding, etc., in which the paint or wood-finish is required to be cut in, at its terminal edge, the provisions of Rule 4 are to be observed.

As already stated and shown, there are various methods of getting at one and the same purpose. Take measurement of a surbase, and one way is to take actual measure and add four inches for cutting in at top and bottom. Another way is to take lineal measure, and if the base is ten inches wide, call it a foot, because painting the extra two inches is not considerable, and when you come to a fourteen inch base, you call it still a foot. And thus the matter is equalised. In the latter way nothing is added for cutting-in at top and bottom, and this avoids disputes with customers, who may not see the justice of charging for cutting-in.

v.8-9
Canadian

and

Other conditions enter into the problem of measuring work that still further embarass the measurer. The work may be new or old, and in various stages of newness and decay. New work differs much in the manner of its preparation for painting, and an old job may be easier to repaint than a certain new job. The proper way to provide for this would be to have a separate schedule for each class of work. Thus new and old work might be divided into class A, best condition for painting; class B, fair condition; class C, poor condition; class D, bad condition. This would be put under proper heads, as "new work," "old work." Removing old paint by burning it off should be noticed under its proper heading, or removing by alkalies or any similar treatment. It is worth 30 cents a square yard to burn off paint from a plain surface.

In measuring balusters it is very difficult to lay down a fixed rule of measurement. The rule is to allow double measurement for square balusters, and treble for round. Say a row of balusters is 12 ft. long and 3 ft. high, including a rail on top. The tape line is run over the rail from one side to the other, giving 6 ft. This being doubled gives 12 ft., and multiply the length, 12 ft., by this height of double 6 ft., or 12 ft., gives a total of 144 ft. The turned baluster would give 216 ft. Balusters, of course, differ in style, and hence much must depend upon the judgment in measuring. Again, take window blinds, or Venetian shutters. If these are large the profit of painting them by the square yard will be large, while doing small blinds the same way will hardly pay, especially at the hands of a slow workman. Some painters, in measuring the front of a house, say, estimate the job "solid," taking no account of windows. Others count windows separately. It certainly takes longer to paint a building that has many windows than one having but few, and unless some separate account is made it is hard to say how a correct estimate can be made. In doing roofs that have turned up seams, say an inch high, it is proper to add two inches for each seam the roof contains. Estimating gable ends, peak roofs, and the like, some halve the distance from the square of the building to the apex of the roof, and count same as below the square. Others, again, taking into account the trouble involved in doing such work, count the work as square.

Other elements affecting cost of doing work consist in such matters as number of colors; number of coats; tints to match certain objects, as wallpaper, carpets, etc.; graining, its quality; varnishing, quality of varnish. The work on a fine house will necessarily cost more to do than that on a cheap house, and these matters can be arranged under the headings suggested and relating to new and old work of various conditions of finish. It is not difficult to lay down fixed rules that will apply to the great bulk of the work done, but the exceptions are the trouble. Graining may be classed as first, second and third quality, or fine, good and "knock-off," as some grainers call quick, cheap work. There can scarcely be any room for other character of work between these classifications.

Having set a standard price on such work, say two shillings per yard, then for first-class work add 25 per cent., and for third-class or cheapest work deduct 25 per cent. This is a sort of sliding scale, and might be made to apply to painting as well.

Painters ought not to guess at the cost, nor take the architect's figures for it. Nor should they conclude that because a certain similar job cost so much to do, this particular job will cost about the same. Estimate too high, and the job is lost. Too low, and money is lost. There is a certain arrangement among some of the master painters in the States whereby incorrect estimating is somewhat obviated. An association is formed, and when a member makes a bid or tender for a job, he lays his figures before the association, as does any other member estimating on the same work. An average is made of these bids or tenders, the man nearest that average getting the work, or if not near enough, his price is raised to the average, and the others withdraw from the contest. But they are not absolute losers. Indeed, the low bidder is the gainer, because he is sure of receiving a certain percentage of the amount of the successful man's contract price, whereas had he secured the work at his own figure, he would doubtless have had his work for nothing. This plan works very well. It nullifies the evils of competitive bidding, and even those who fail to get the work get a percentage of that work's profits. And when the owner of the work understands this scheme he likes it, too, because he knows that he is getting his work done at a fair price.

THE FOUNDATIONS OF THE NEW YORK CATHEDRAL.

On a commanding eminence in the outskirts of the Morningside Park, New York City, work has been progressing for some months upon the foundations for a costly and imposing cathedral, which is designed to be one of the largest and finest, if not the most beautiful and important of modern ecclesiastical structures. Its site is on the crest of a bluff overlooking a large part of upper New York and the Hudson river. It lies between Morningside Drive and Amsterdam Avenue, and extends from One Hundred and Tenth to One Hundred and Thirteenth Streets, affording ample area for the display of its architectural beauties, while the handsome buildings of Columbia College and of St. Luke's great hospital adjacent will be consistent environment. The finished building will be about 320 feet by 290 feet in extreme dimensions, about as large as St. Paul's in London, and will have a grand tower about 445 feet high. At present the construction is begun only upon a small part of the edifice, viz., upon the tower and its adjacent choir, for which the foundations are now well advanced.

As the rock outcropped in places at the site, it was believed that solid and most satisfactory foundations could be very easily secured, but when excavation and levelling was begun it developed a singular and troublesome condition of affairs, which has necessitated much delay and expense. The stone, the familiar gneiss of the locality, was disposed in very irregular masses, the formation of which was almost like waves, the surfaces of the outcropping ledges sloping down in places at a sharp angle and intersecting at the vortex of troughs 20 to 45 feet below the surface. At other places the surface of the solid rock was not so deep, but was very irregular, and much of the upper part of the stone was found loose and disintegrated or filled with pockets of earth and clay, so that considerable excavation was necessary to secure an enduring and reliable platform on which to impose the heavy and extensive loads of the enduring structure.

It was, therefore, determined to excavate several large pits which should each contain the piers for several adjacent important foundations. The earth and loose and unsound rock were all removed, and the solid rock faces exposed roughly dressed and scrupulously cleaned with wire brushes, then thoroughly washed with hose and brooms and the space filled up to elevation 112 (an average depth of 15 feet and a maximum depth of 45 feet) with a uniform mass of concrete, upon the level surface of which the cut granite pier footings are laid. The surface is nearly continuous, interrupted only by some recesses where the distances between pier footings were largest, and to leave canal-like passages about 12 feet deep for pipes, etc., although up to elevation 100 feet no openings at all were left in the concrete laid. The great tower itself rests on arches sprung high in air from four smaller corner towers with flying buttresses. Each of these four towers transmits an estimated pressure of 17,000 tons to the bed of concrete which supports its base, 38 feet square, thus producing a load of about ten tons per square foot. To distribute this and proportionate load from the rest of the structure, great pains have been taken to secure a solid and homogeneous bed. To this end the concrete, which is composed of cement, sharp sand and gravel in proportions of 1, 2 and 3 respectively, was thoroughly mixed quite dry and rammed by 20-pound rammers from 10-inch horizontal layers to 8-inch thick layers, and till the water was flooded to the surface. When night came the layers were terminated wherever it happened with long sloping edges, and when work was resumed in the morning the whole top surface was plastered with a mortar made 1 cement and 2 sand, upon which the next course of concrete was laid and rammed exactly as if setting blocks of stone. The concrete became very hard over night, and this method is believed to have secured a real monolithic condition throughout the whole mass of concrete, which now contains about 11,000 cubic yards, and will require about 2,000 yards more to complete it.

Quartz gravel, 1½ to 2 inches large, and sharp sand, both from Port Eaton, on the north shore of Long Island, are used for the concrete, which is mixed of such consistency as to be just capable of moulding into a ball in the hands. The cement (17,000 barrels of which has been used so far) is Aalborg's, Alsens, Germania, Mannheimer and Silica-Portland. The latter is used almost exclusively for masonry mortar. The cement is stored in two large houses on the site. A sample of cement taken at random from one barrel in every ten is tested on a Riehle 1,000 lbs. machine by the engineer's inspector in a laboratory equipped at the site. Here about 600 briquettes are kept hardening under water for one, seven and twenty-eight day tests. Very little of the cement has had to be rejected, much of it with three parts of sand developing a tensile strength of over 200 lbs. in seven days. The usual tests of fineness and rapidity of setting are performed with customary standard apparatus.

The foundations will contain about 5,000 yards of dimensioned granite masonry. The concrete work is notable for its unusual magnitude, the manner in which it is executed, and for the character, arrangement and operation of the plant for making and handling it. All material is carted to the site and delivered directly to the derricks, to the storehouses, to the working platforms, or is distributed by the central track. All the concrete is mixed in two standard Sooysmith machines, set on opposite sides of the work so as to deliver their product close to the place where it is required. Each mixer is set with the top of its hopper about level with a working platform that closely surrounds it at the surface of the surrounding ground, and upon which materials are delivered by wheelbarrow and derrick and placed in bins. Men with shovels keep it continuously fed into shoots that carry it down to a platform about 6 feet below, upon which rest the lower ends of three inclined chain and bucket conveyor elevators that are driven at the same speed, about 2 feet per second, by a small vertical engine on the same platform. This engine also drives the mixer. All are driven by belts which will slip and allow the machinery to stop when obstructed rather than break as a gear would. One elevator is encased throughout in a tight wooden case, the lower part of which is filled with loose cement, which it brings up and empties into the upper part of the mixer hopper. The next elevator is on the opposite side of the hopper, a couple of feet nearer the discharge end, and delivers sand from a heap at the foot of the chute below, where two men are constantly in attendance to see that each bucket is level full. The third elevator is 2 feet further away, on the same side as the cement elevator, and similarly served by two men, and delivers gravel. The mixer is about 12 feet long over all, and inclined about 1 in 12 down towards the discharge end. Its shaft makes about 20 revolutions per minute, and is fitted with about sixty inclined bevelled radial cast-iron arms that mix the materials very thoroughly, even before they are wet by a man with a hose-nozzle just opposite the gravel elevator, and considerably more afterwards. The elevator buckets each hold about 1 cubic foot and discharge their contents over to the further side of the shaft. They are set at distances apart on their chains inversely corresponding to the proportionate quantities of material they are to furnish for the concrete. Below the mouth of the mixer is a third and still lower platform, upon which are two short 30-inch gauge tracks, about 4 feet apart centre to centre, each with one car upon it. A car upon one of these tracks is run up under the mouth of the mixer and a little to one side of its axis, but parallel with it, and the mixer delivers continuously into its 1-yard iron bucket (which it can fill heaping full in a minimum time of about two minutes) by a flat wooden chute about 4 feet wide and 6 feet long, mounted on a horizontal axis just below the mixer and in a vertical plane through its own axis. This chute is operated like a butterfly valve, first tipped up to an angle of 45 degrees with the vertical on one side, so as to divert the flow from the mixer all into the bucket on the right-hand car. When that is nearly filled a bucket and car are pushed up on the left-hand track. The top of the chute is revolved 90 degrees to the right, and the discharge from the mixer is instantly diverted into the empty car, and the full one is run off and taken by the derrick, which can usually swing it to the required place and empty it immediately. Sometimes hauling and the delay of materials threaten to hinder the work, and such occasions are taken to lay concrete most remote from the mixers that takes more time or the use of two derricks to handle it. When the concrete has set it is kept constantly well sprinkled for several days.

About twenty men are required in direct attendance upon each concrete mixer, and about forty-five more are required for all the concrete work, tamping, wheeling, hoisting engines, etc., for each machine's maximum

v.8-9
Canadian
archi
and

product. As high as 260 men a day have been employed on this contract, the active prosecution of which was begun on April 1. The highest output of one concrete mixer has been 262 yards of tamped concrete, or 328 heaped 1-yard buckets of loose concrete in 8½ hours. Vertical faces of concrete are obtained where necessary by 1-inch mould boards secured to well-braced studs outside.

The principal plant consists of the two concrete mixers, driven by two 15 horse-power vertical high-speed engines, a Murray and a Safety; two horizontal tubular water bottom 50 horse-power Lidgerwood boilers, one Cameron duplex steam pump with 3-inch suction, which has been needed only to remove the rain-water, one derrick, 70-feet mast and 65-feet boom, all with four steel rope guys and running tackle, good for 10 tons load each. Two of them have the Buffalo standard fittings and the remainder those of the St. Paul Hoist and Derrick Company, and all of them have new round sticks of Norway pine spars from Brooklyn yards. They are all painted white, and present a neat and handsome appearance. They are operated by six double-drum Lidgerwood hoisting engines, two of them with individual boilers. Messrs. Heins & LaFarge are the architects, and Gen. William Sooy Smith, of Chicago, is consulting engineer of the cathedral, and the above-described work is being executed by Sooy-smith & Co., contracting engineers, of New York, upon a commission contract. The earth and rock excavation was done by J. D. Crimmins and J. J. Hooper respectively, and John Pierce has a contract for dimension granite for piers, etc.—Builders' Reporter.

UPRIGHTING A TALL BRICK STACK.

UNDER the above heading Brick describes the method by which Mr. E. W. Seamans, of Grand Rapids, Mich., succeeded in righting, at the Standard Concrete Manufacturing Works, at Norristown, Pa., a tall chimney that had declined considerably from the perpendicular:—

At the company's works there is a brick smokestack 122 feet high and 11 feet square at the base, the walls are 36 inches thick and the whole structure weighs not less than 400 tons. Some time since the top of the stack began to lean over and, when it inclined 45 inches from a vertical line, it was felt to be too dangerous to allow to go any further.

It was agreed that any attempt to pull it back to a perpendicular position would certainly cause its destruction. Contractors would not undertake the task of righting it for any less sum than the cost of pulling down and rebuilding it. So Mr. Seamans thought out an entirely original scheme for straightening it; this he had to carry out himself, as no one would take the risk.

To raise the sunken side of the stack was an impossibility. The only course left, therefore, was to sink the other side four and one-half inches. To accomplish this ten and one-half inches of brick work was removed from the foundation on three sides. As the bricks were removed square blocks of wood were inserted, one after the other, until three sides of the towering mass of bricks rested on wooden cubes. Between the blocks supporting the stack temporarily substantial brick piers six inches high were built, leaving a space of four and one-half inches between the top of the piers and the bottom of the undermined brick-work.

The foundation was now in readiness for the culminating feat, the removal of the wooden cubes, which, successfully effected, the side of the stack would be lowered to the piers prepared for supporting it while the interstices were bricked in. The blocks had to be removed gradually and simultaneously.

Each block was ignited and all were kept burning briskly. If one burned faster than the others the fire on that particular block was quenched until the others reached the same stage of incineration. Thus all were made to burn uniformly, and as the blocks were being reduced to ashes the stack slowly righted, until the last ember died out, when its top was on a vertical line with the base.

The entire work consumed one day. The reduction of the wooden blocks to ashes required an hour. In that time the top of the stack moved forty-five inches, but so slowly that men with powerful field glasses could not detect the slightest motion.

PERSONAL.

Mr. A. M. Ross, senior member of the firm of Ross Bros., painters, Hamilton, Ont., is dead. He was born in that city in the year 1838, and worked for a number of years in the car shops of the Great Western Railway. After the death of his father he took charge of his business, and conducted it with his brother.

There is much anxiety on the part of the friends of the Hon. Mr. Harty, Minister of Public Works for Ontario, owing to the conflicting reports regarding the condition of his health. It is hoped, however, that he may be successful in his effort to regain health, and be able in the near future to again resume the active duties of his Department.

Mr. A. M. Calderon, the well-known architect of Ottawa, has taken unto himself a bride, in the person of Miss May Bate, daughter of Mr. Newell Bate, merchant of the same city. The wedding took place on the 23rd of October, at Christ Church, the venerable Archdeacon Lander officiating. Mr. and Mrs. Calderon left on a short tour in the States.

The death occurred at Victoria, B. C., last month of Mr. William Wilson, at the advanced age of 94 years. Deceased was born in Banff, Scotland, where he learned the mason's trade, coming to Canada at the age of 29 years and settling in the city of Quebec. For upwards of half a century he carried on business as a builder and contractor, and erected a number of important buildings in that province.

At St. John's church, Toronto, on the 6th of October, Mr. Frank S. Baker, of the firm of Curry & Baker, architects, was united in marriage to Miss Florence Mary Kenrick. The ceremony was performed by the Rector of the church, the Rev. A. Williams, in the presence of a large assembly. Mr. Baker and his bride are spending their honeymoon in the Eastern States. We join our congratulations to those of their numerous friends, and wish them a happy and prosperous voyage through life.

On the 22nd ultimo the death occurred in Toronto, after a lingering illness, of Senator John Ferguson, M. D. Deceased was born in the county of Middlesex, Ont., in 1839, and was at one time a prominent contractor. He built a portion of the New York and Oswego Midland Railway, and the Galt and Berlin road was also constructed under his supervision. He was given the contract for the enlargement of six miles of the Welland canal, and, with Mr. Robert Mitchell, built the larger portion of the waterworks system in Toronto and also the works at St. Catharines.

Every poor speller seems to finally go into the sign-painting business.—Atchison Globe.

A striking instance of the durability of timber, under certain conditions, was afforded during the excavation for the foundation of the Bowling Green Building, New York. A line of spruce piles was discovered at some distance below the surface of the ground, which, as far as we can learn, were placed in position about 150 years ago and actually formed a bulkhead, the tide then reaching this point. These piles, upon examination, were found to be perfectly sound, and to all appearances would have been just as sound and good 150 years hence.

In his selection of typical workmen Mr. Gladstone has given preference to those in the building trade. The editor of the British Workman having asked Mr. Gladstone for a message to working men which is to be reproduced in fac simile in that ournal, has received one, of which the following is the most interesting paragraph: "I think there is among parents in what are called the laboring classes too much anxiety to take their children out of hand labor and to transfer them to head labor. But a good deal of what is called head labor is not worthy of the name, whereas hand labor is, in many branches, capable of great elevation. Take, for example, the connection of the mason's trade with the sculptor's art, and the relation between the carpenter and the wood-carver. Further, the higher hand labor is very much better paid than the lower head labor. It would be of great utility to laboring men if they would think this through for themselves."

CANADIAN ARCHITECT AND BUILDER.

VOL. IX.—NO. 11. NOVEMBER, 1896 { PRICE 20 CENTS $2.00 PER YEAR.

—THE—

CANADIAN ARCHITECT AND BUILDER,

A Monthly Journal of Modern Constructive Methods.

(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD).

PUBLISHED ON THE THIRD THURSDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

C. H. MORTIMER, Publisher,

Confederation Life Building, - TORONTO, CANADA.

Telephone 2362.

Branch Office: NEW YORK LIFE INSURANCE BUILDING, MONTREAL.

Bell Telephone 2269.

SUBSCRIPTIONS.

The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.

Prices for advertisements sent promptly on application. Orders for advertisemnets should reach the office of publication not later than the 12th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of value to the persons in whose interest this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publisher of any irregularity in delivery of paper.

ONTARIO ASSOCIATION OF ARCHITECTS.

OFFICERS FOR 1896.

PRESIDENT	H. B. GORDON, Toronto.
1ST VICE-PRESIDENT	J. GEMMELL, Toronto.
2ND VICE-PRESIDENT	JOS. W. POWER, Kingston.
TREASURER	EDMUND BURKE, Toronto.

COUNCIL:

F. J. ALEXANDER	Ottawa.

JOHN L. PHILLIPS, Secretary.

TO ADVERTISERS.

For the benefit of Advertisers, a copy of this journal is mailed each week to persons mentioned in the CONTRACT RECORD reports as intending to build, with a request to consult our advertisement pages and write advertisers for material, machinery, etc.

A Point of Law.

It may be a matter of some interest to our readers to know what legal rights are possessed by persons who may desire to move a building along the public streets from one situation to another. The Supreme Court of New Jersey expressed the opinion that the use of a public highway for such purpose was not within the rights enjoyable by the public in a public highway for the purpose of travel. The Supreme Court of Indiana decided that although citizens had the right to ordinary use of the streets they could not interrupt traffic or discommode the public by tearing down electric wires in order to remove buildings along the streets. In the case of the Toronto Street Railway Company vs. Dollery, it was held that a person cannot lawfully blockade the tracks of a railway company by moving a building.

Teaching of Architecture at McGill University.

We have the pleasure to present in this number a personal sketch and portrait of Professor Capper, who has been chosen to fill the newly established Chair of Architecture at McGill University, Montreal. Professor Capper was honored by being called upon at the very outset of his career in McGill, to deliver the annual university lecture. It will unquestionably be gratifying to the profession throughout Canada to observe that the teaching of architecture has been given a place side by side with instruction in engineering and the other professions at the foremost seat of learning in the Dominion. A perusal of Professor Capper's address gives the impression that the new Department of Architecture has been entrusted to competent hands, and that at its head is a gentleman inspired by high ideals and a determination to impart as far as possible those ideals to his students and others with whom he may be brought in contact.

Proposed new Building By-Law for Montreal.

Allusion was made in our October number to the fact that up to that time the City Council of Montreal had taken no action with reference to the new building by-law which was drafted and submitted for their approval early in the year by the Province of Quebec Association of Architects. It is gratifying to learn that during the last month representatives of the Association were invited to join the aldermen in considering the matter. We have not learned what progress was achieved, but now that a beginning has been made in the direction of dealing with the subject, we trust that the necessary time will be given for its thorough consideration, and

that in the near future the Council will pass a by-law giving effect to the valuable recommendations made by the architects, which are the outcome of months of effort for the public welfare. We hope that the City Council of 1897 of Toronto, will also feel it to be their duty to either approve or reject the suggestions presented by the Ontario Association of Architects for the improvement of the existing by-law, which is admittedly defective in many important particulars.

Modern Toronto Architecture.

The many large buildings which have been erected in Toronto within the last six or seven years, and those which are in process of erection at the present time, have given a metropolitan character to the city which it did not formerly possess. The appearance of most of these buildings, including the new City Buildings and the Foresters' Temple, now nearing completion, is satisfactory. It seems to us subject of regret, however, that the important structures last mentioned should have been situated in such close proximity to each other. Both would have gained in appearance had they been farther apart. The view of the new city buildings at present obtainable from Bay street is very meagre and unsatisfactory indeed, partly due to the towering structure at the north-west corner of Bay and Richmond streets, which has reached a height of eleven storeys. It would add very much to the appearance of both of these important buildings if the city should decide to expropriate sufficient land to enable Queen street to be widened opposite the new city buildings, thus removing a number of the dilapidated old structures which at present disfigure the locality and render it impossible to obtain a satisfactory distant view of the new buildings. The new city buildings are now sufficiently advanced to show that they will present, when completed, a character at once imposing, pleasing and refined in comparison with the American creation in Queen's Park. The statement has been published within the past few days that the Duke and Duchess of York will take part next year in the ceremonies attendant upon the formal opening of the building.

Fire Retardent and Light Diffusing Properties of Wired and Ribbed Glass.

Brief mention was made in our last number of recent tests which show the superior light diffusing qualities of ribbed as compared with plain glass. At the request of our readers we have obtained further information on the subject, for which we acknowledge our indebtedness to the Boston Manufacturers' Mutual Fire Insurance Co. The President of this company is Mr. Edward Atkinson, a well-known authority on methods of fire proofing. Mr. Atkinson's company recently arranged for a complete investigation of the subject at the Massachusetts Institute of Technology. From photometric comparisons made at this institution of the intensity of the light from two windows similarly situated, one glazed with plain glass and the other with ribbed glass, the light-diffusing properties of the latter were shown to be from fifty to two hundred per cent. greater than those of the former. While the general resultant direction of light entering through a window is downward, at an angle of 40 to 50 degrees, the action of the ribbed glass appears to be prismatic, the greater part of the light falling upon it at any point being refracted and spread out into a fan-shaped beam. The horizontal ribs tend to throw the light which would otherwise fall to the floor far into the room, while the vertical ribs spread out the light on both sides. The relative effectiveness of light is much greater where the light is derived indirectly than where it is derived directly from the sun. Heat appears to be diffused on the lines of the light, and while the same amount of heat may pass the ribbed glass that would pass through clear glass, it is so much better distributed as to give the effect of a cooler temperature. The fire retardent properties of wired glass have also undergone investigation by the same company, and the results obtained are both interesting and valuable. Glass of this description, heated to a red heat, so that a piece of paper held against it on the outside was easily ignited, was in this condition showered with cold water. The result was found to be that while the glass was cracked into countless pieces it still adhered together, forming one sheet. The following conclusions are drawn from the test: (1.) Wire glass can safely be used in skylight (on the main buildings of factories or works) and in such will withstand a severe fire and will not give way when water is thrown on it. A wooden framing for skylight, covered with tin, all seams lock-jointed and concealed nailed, is superior in fire-resisting quality to iron framing. (2.) Wire glass in wooden sash, covered with tin, all seams lock-jointed and concealed nailed, can be safely used for windows toward an external exposure. (3.) Wire glass can be safely used in fire doors to elevator shafts and stairway towers where it is necessary to light said shafts. (4.) In office buildings, hotels, etc., where it is undesirable to have elevator shafts entirely enclosed and dark, wire glass permanently built into brick or terra cotta shaft, or arranged in wood, metal covered frame can be safely used. (5.) Wire glass plates, securely fastened in standard fire shutters, can be safely used toward an external exposure. In this case the fact that a possible fire in a building, all windows of which are protected by fire shutters, can much more readily be detected from the outside through the wire glass, is of importance. We have previously referred to the manner in which buildings are destroyed as the result of the windows cracking and falling in, resulting in currents of air rushing in through the openings, either carrying flame into the building or fanning into life the fire slumbering within it. The use of wired glass, which would be less costly and much more sightly than iron shutters would tend to greatly lessen the danger of the destruction of buildings from this cause.

"MODERN METHODS" OF A "PROGRESSIVE ARCHITECT."

We have from Hamilton the prospectus of one who calls himself a "progressive architect" doing business by "modern methods." The scheme laid bare of all the puffery with which he surrounds it is simply the issue of plans and specifications in connection with the mail order department of a departmental store. The prospectus contains cuts of several houses, of the merits of which, as there are no plans given, we are not able to form an exact opinion, but the offer frequently repeated throughout the prospectus "this plan can be reversed free of charge if desired" not only cannot be said to be consistent with good planning, but is truly unprofessional. The architect is, like the doctor or lawyer, a professional adviser; that is to say, the client comes to him as the repository of special knowledge, and out of his knowledge he advises the client for the client's interest. This progressive architect, however, appears to have cut loose from all this; his business is merely to sell, and the client may look after himself. He must know, if he is really an architect, how important to a plan is the right aspect of its rooms, and how impossible it is to reverse a good plan without completely overthrowing all that made it good. That a kitchen should be in the cool part of the house, a dining room where it will get the morning sun, that a drawing room is best with a western light, that bedrooms should not look to the north if it can be avoided, nor a porch be set to catch the northwest winds, nor a furnace placed on the lee side from the same cold quarter are all commonplaces of house planning. Yet this vendor of plans, if in his unprogressive days he has designed a house with the dining room in the south and the kitchen in the north, is quite willing to reverse the plan now and introduce a modern method of baking the cook in summer in a south kitchen, as a set off to freezing the householder at his breakfast in winter in a north dining room and to say nothing to his client about the changed state of affairs. It would have been all right if the prospectus instead of reading "This plan can be reversed free of charge. Regular professional fee is $53. Our price is only $10," had read "Our price for this plan is only $10, but if your lot faces the other way do not on any account order this plan, but have a house planned for your own lot at the regular professional fee of $53, and you will find that the difference, which is only $43, will pay for itself over and over again by giving you a house that you can live in with comfort or keep always let." In dealing thus honestly with the public in offering his old plans our progressive architect would have secured confidence for the branch of his prospectus entitled "Plan of Your Own." Here he offers always in connection with the mail order department—to "work up a sketch" from instructions or a rough plan. Consideration of the price is in this case reserved until the sketch is made, and though under ordinary circumstances we have no wish to interfere with any man's method of doing business—since our prospectus writer introduces his own way of doing business to the public by way of an attack upon the usual methods, we can only say that, in comparison with this method of dealing with the question of cost, the usual method of percentage fees, clumsy as it is, seems safer for the client.

AN EDUCATIONAL STANDARD FOR ARCHITECTS.

With the election of Major McKinley to the Presidency by a substantial majority is accomplished the last of the departures in the public affairs of the United States and our own country, which business men have promised would be turning points in business affairs, and we may hope now for the beginnings of revival in trade.

When the building trade begins to look up we fancy there will be noticeable a greater merit in the buildings than in those erected during the last period of energy. Although building has been slack during these last six years, architects and architectural students have not been idle. The architectural societies of Ontario, Quebec and British Columbia were started at the close of the boom times, and, though they have been much hampered by the bad times, they have done enough work to justify their existence. The education of an architect, which before 1890 was an indefinite matter, is now scheduled. Every student in these provinces may hear exactly what he ought to know; has books and opportunity provided, and the guide and stimulus of a system of graded examinations. The architects who have been engaged in forming the libraries, ordering the curriculums and conducting the examinations, have themselves profited by being concerned in these things. They have also had their conventions, have profited by hearing papers—still more, no doubt, by writing them—and perhaps most of all by the mere fact of meeting together to hear and discuss them. Architects know one another now as they did not formerly; there is a greater interchange of ideas; the sociable condition, which is essential to the development of all art workers, is much better established now than formerly. In fact, the architects have had an enforced opportunity for reflection, and the associations were instituted just in time to give them the means of profiting by it. We may therefore consider that in the space between the good times which are past and the good times which are coming on, the educational ideal of architects has been recognized, and the architects themselves are better conformed to it than formerly. As the next period of prosperity will see the erection of more important and permanent investments than the previous period, there is cause for satisfaction that the education standard has been raised. The pity is that it has not been placed in a position from which there is no retreat. If the proposal brought forward last year in this province to make the title "architect" a degree accompanying a diploma, had been put through the House, we should now be able to look forward to the next period of building with the confidence that at least all the juniors concerned in it—and in their hands would usually be the actual draughting and detailing—would be trained men. Great results might have flowed from a fundamental measure of that kind—indeed may yet flow from such a measure, for it is likely that the measure will not be dropped after having so nearly met success.

It is impossible for anyone who has at heart the growth of a good style of building in the country not to wish that the architectural societies, or some other bodies, were made the agents of the government for the education of all architects. Each pile of building material brought to a site depends upon the architect for its ultimate value as much as does a lump of clay upon the hand of the potter. The architect's work is the creation of property out of raw material, and it is but a short-sighted policy that takes no account of provision for his training.

It is true that all building in the country is not done by architects; indeed, it is probable that if a line of demarcation is drawn between architects and builders the country builder and designer will have a status which he never had before. But to throw a line of building more definitely into the builder's hands for design as well as building is more likely than otherwise to stimulate his taste for good design. In the older countries there has been excellent work done by builders in a traditional manner of work. In any case, he is bound to rise in his style if the architects do. He is a quick and skilful imitator. It is his manner of designing. His facility is with his materials; his ideas he gets from example, and though it is the custom to abuse the builder's design, he has usually much practical sagacity, and knows a good thing when he sees it. At the back of the builder's design is always the architect, and the more a good style of building is diffused among architects the better will

be the general run of building for which architects are not required.

So that after all we have to look to the architect for the character of building in the country, and we hope that he has made the most of his recent leisure and of such opportunities as have been offered to him to prepare himself for his responsible function of creator of property.

MR. A. T. TAYLOR, F.R.I.B.A.

We have the pleasure of being able to present to our readers an excellent portrait of the new president of the Province of Quebec Association of Architects, Mr. Andrew T. Taylor, F.R.I.B.A. Mr. Taylor has been a most enthusiastic and stedfast worker in connection with the P. Q. A. A. for the promotion of the interests of architecture in the province of Quebec, and has thus honestly won the position of honor to which he was elected at the last annual convention of the Association.

Mr. Taylor was born and educated in Edinburgh, Scotland. He served his articles with Messrs. Pilkington & Bell, and subsequently entered the office of the City Architect of Aberdeen. Following this he was for a time with Mr. Joseph Clarke, F. S. A., in London, diocesan architect and surveyor for Canterbury, where he had large experience in the restoration of old parish churches and church work generally.

Mr. A. T. Taylor, F.R.I.B.A.
President of the Province of Quebec Association of Architects.

Mr. Taylor was elected an Associate of the Royal Institute of British Architects in 1878, and was made a Fellow of the Institute in 1889. He studied in the architectural school of the Royal Academy under Mr. Phene Spiers, gaining the Royal Institute medal in 1874 and again in 1881, and also a Soane medallion medal. He passed the examinations and qualified for the post of a district surveyorship. After having travelled over the continent of Europe for some time he entered upon the practice of his profession in London, where his partner, Mr. Gordon, now is.

In Canada a large number of buildings have been erected from his designs, amongst others, the Macdonald Engineering and Workman Buildings at McGill College, also the Physics Building, the Redpath Library, the most recent Medical Building, and just now, the new Chemistry and Mining Buildings at the same place; Bishop's College School, Lennoxville; the Diocesan Theological College, Montreal—an illustration of which appears in this number—many banks, including buildings for the Bank of Montreal in Vancouver, Calgary, Regina, Perth, several in Montreal, including the entire renovation of the head office of the Bank of Toronto, Montreal; the renovation of the Montreal General Hospital; a large number of residences, including the magnificent house of the Hon. Senator Drummond; the new Art Gallery, Montreal, etc.

Mr. Taylor obtained the second place and premium in the important competition for the Glasgow Municipal Buildings, in which over 116 competitors took part, and was selected to be one of two experts in the competition for the British Columbia Government Buildings at Victoria. He is Professor of Architecture at the Presbyterian College, Montreal, has been a member of Council of the Art Association for many years, academician of the Royal Canadian Academy, etc.

Mr. Taylor is also the author of a book on the "Towers and Spires of Sir Christopher Wren," and joint author of the series of "Dominion Drawing Books" used in the Protestant schools of the province of Quebec.

THE ONTARIO ARCHITECTS' BILL.

To the Editor of the Canadian Architect and Builder.

Sir,—Your desire to obtain special legislation for architects in Ontario is to be commended, but it seems to me that in the form this bill has been presented and as often rejected by the Ontario Legislature, such a law would not be so much in the interest of the public as in favor of a few of the already self-dubbed architects. As a teacher of architecture I decidedly wish there was an examination conducted by an independent and recognized public examining body, of such a nature as would be a guarantee that those who had passed this test of knowledge were worthy to rank on an equality with other professional men; and whatever subjects were optional, it should be compulsory that the candidates pass an examination in the strength of the various building materials and the modes of constructing the same in a scientific manner; that is, having due regard to the strength, strain, and stress of the several parts, individually, and of the whole when combined as a whole, so that such structures might be safe under all ordinary conditions of loading and wind stress on the one hand, and free from undue waste of material on the other. The public, I feel assured, would be in favor of, instead of being opposed to, such legislation.

You seem to infer that the public are not opposed to the passage of the bill. I know for a fact that decided opposition exists, and have tried to ascertain why this is so, and find 1st, as the bill was framed the present self-dubbed architects were to be architects still, but with authority to formulate all sorts of conditions to prevent younger and better trained men from entering the "ring;" 2nd, the bill as I understand it demands that candidates must have attended the School of Science in Toronto or have served five years in the office of a self-dubbed architect, and they have in consequence associated the School of Science as being an institution of about the same status as many of these men.

The era of "articled pupils" is no longer existant, and the meanness of the proprietors of almost numberless offices has brought about this state of affairs. I ask, is it just to a young man after he has attended public school, collegiate, and perhaps university, to enter an office as a pupil, when in reality he is an office drudge?—who, by the way, is not free to break his part of the agreement as soon as he finds the principal has no time to teach him anything. He must "pick up" as best he can a knowledge of the business out of office hours, as he is kept at specifications, tracing, etc., keeping office tidy, being there if any person happens to call when the proprietor is out. If office work is slack he may be allowed to copy a perspective drawing, which has already been published by the Canadian Architect and Builder, during his office hours, and when his five years of such drudgery is over he may perhaps be given his railway fare to expatriate himself to the United States, or endure every obstacle possible being raised to prevent his starting an office in Ontario.

Sensible people now do not article their boys who intend to follow the profession of clergyman to a worthy divine, but they send him to school, and parents of would-be architects now do the same. I claim that in this school our architectural students acquire more knowledge in two years than they do in the average office in five years, and on leaving get good appointments in the States.

After calling the attention of your readers to the weak points in the scheme, allow me to suggest a few remedies:

1st. Let the Toronto University or the Hon. Minister of Education grant degrees for architects, which I would suggest be in the following order: A. Arch. (Associate in Architecture), for students; B. Arch. (Bachelor), for 3rd year students; M. Arch. (Master); D. Arch. (Doctor). Any person should be allowed to be examined, no matter from whence they came or wherefrom they obtained their knowledge, and a diploma should be given to all who can pass the prescribed examinations.

2nd. Make the owners of buildings, whether such are already built or in process of construction, responsible for damages to employees and other persons having business in the vicinity of such building at the time of total collapse or falling of any part thereof.

3rd. Avoid mentioning that people must employ an architect; the public think the Association of Architects want laws to prevent any person whatsoever from even building a shed in a yard or an addition to a barn unless an architect is to be called in and the inevitable 5% charged.

4th. If those architects who have not work enough to keep them and their assistants going all the year round choose to arrange to give instruction (provided they are capable of so doing) to their assistants, let such instruction be paid for by those receiving it; and on the other hand, when an assistant works for an architect his labor is of value, and should be paid for accordingly, either by piece work or by the hour. The best men are the busiest and have no time to teach boys.

5th. If the proprietor of a building is made responsible, and he has employed an architect to put up a safe structure, the proprietor should in turn be enabled to sue the architect for damages should an accident occur.

If the Association will modify the bill on these lines there is no doubt it will pass, and the public will soon judge for themselves the merits of different architects, and no doubt in time the recognized 5 per cent. will go, and less commission will be paid for work requiring but little skill, and more for that which does. Apologizing for taking so much of your valuable space,

S. John Ireland,
Principal Hamilton Art School.

PROF. S. H. CAPPER.

It affords us much pleasure to be able to present to the readers of the Canadian Architect and Builder the accompanying portrait of the first Professor of Architecture at McGill University, Mr. Stewart Henbest Capper, M.A. (Edin.), A.R.I.B.A.

Professor Capper, who is 36 years of age, and consequently at the zenith of his powers, was educated at the Royal High School at Edinburgh. In 1875 he entered the University of Edinburgh, graduating in 1880 as Master of Arts, with first-class honors in the Department of Classical Literature and being awarded the Pitt Club scholarship in Classics. From 1879 to 1884 he

Prof. S. H. Capper.

acted as private tutor and also as private secretary in the household of the British Plenipotentiary at Lisbon and Madrid, and took advantage of the opportunity to study the architecture of Spain and Portugal. From 1884 to 1887 he studied and travelled in France and Italy, being admitted by examination a student of the Ecole des Beaux Arts, Paris. From 1887 to 1891 he practiced as an architect in Edinburgh, and during this period erected a number of important buildings. In 1891 he was elected an associate member of the Royal Institute of British Architects, and shortly afterwards was admitted a university extension lecturer in connection with Edinburgh University. He has given numerous courses of lectures upon Architecture, both historical and technical, in Edinburgh, Perth and Dundee. In 1896 Mr. Capper was appointed examiner in the Faculty of Arts at Edinburgh University for the department of archæology and art history.

We have had the privilege of seeing copies of the testimonials presented by Prof. Capper to the governors of McGill University. They bear the signatures of men of the highest educational attainments in the universities and professional societies of Great Britain, France and Spain, and leave little room to doubt the qualifications of the gentleman who has been chosen to instruct the rising generation of Canadian architects. The architectural students of the future are to be congratulated upon the fact that the means of obtaining a thorough architectural training are now available within the boundaries of their own country.

THE ONTARIO ARCHITECTS' ACT.

In another column will be found a letter from Mr. S. John Ireland, principal of the Hamilton Art School, in which he upholds the idea of exacting a standard of education from architects, but objects to the amendment to the Ontario Architects' Act, by which it has been proposed to effect this end in Ontario.

The intention of the proposed amendment is, briefly: To allow all architects who are at present making their living as architects to continue to call themselves so, but to prohibit after a certain date anyone from beginning to call himself an architect without having undergone a certain process of education. And the education of the future architect is to be accomplished by preparation for a series of examinations, either in private or by attending the School of Practical Science or another training school, and by serving a certain length of time in an architect's office in order to acquire an acquaintance with the practical work of architecture.

Mr. Ireland's contention is chiefly that this period of apprenticeship is unnecessary, and that a school such as his own can turn out architects fully prepared to enter upon practical work. He seems to think, by the way, that graduates of the School of Practical Science are exempted from serving in an architect's office, but this is an error. Their time of service is, however, shortened from five years to three. He draws a very gloomy picture of the student's work in an architect's office, and it is true that there are good offices and bad offices; but if Mr. Ireland thinks that time is wasted which is concerned with specifications, drawing plans, keeping office files and arrangements in working order, seeing persons who call in the absence of the architect, and even in setting up and rendering perspectives, he knows little of the nature of the experience that is necessary before a young man, however high he may have ranked at an art school, is fit to undertake the practical work of the business responsibilities connected with putting up a building. The legislature is concerned with the rights of the public as much as with those of the student (if indeed the right of a student to balk his own education is at all one of those rights for which legislators have consideration), and we fancy it will not see its way, in the case of any bill which is brought before it, to abolishing the enactment that students shall serve some time in the office of a practising architect.

Mr. Ireland seems also to think that the legislature should abolish what he calls the "self-dubbed architect," but how to do this is a difficulty. The "self-dubbed architect" is simply the existing architect, and to abolish him would be to abolish vested interests. It is not the doing of anyone interested in the bill, but of the tradition of English legislation that "as the bill was framed the present self-dubbed architects are to be architects still." To take every occasion of alluding to them as "self-dubbed" is therefore unkind of Mr. Ireland; but to go further and allude to them as a "ring" which would try to keep out younger and better trained men, or to allow himself to conceive the idea that an architect would dismiss his student with the gift of his fare to the United States in order to get him out of the country, or to suppose that students would have to "endure" the raising of obstacles to prevent their starting an office in Ontario, is to imagine a lowness of mind in the members of an artistic profession which we should not have expected to find attributed to them by the principal of an art school. It is worth noticing in this connection that the objection which has been raised in England to making the title "Architect" obtainable only by examination is not that existing practitioners will repress younger men, but that the profession will be flooded by young men because it will have risen in dignity. So with many men there are many minds. But it is about details. The main idea that architects should be properly qualified for what they profess, and that the title "Architect" should be assumed only as a degree, representing the attainment of a certain standard of education and training, is coming to be a matter of general agreement, and Mr. Ireland appears to be prepared to approve of legislation, which would properly attain this end.

In the latter part of his letter Mr. Ireland gives some items of advice to intending legislators or promoters of legislation. Article 3, to "avoid mentioning that people must employ an architect," emphasizes what is, we fear, a very common misapprehension. There are no doubt many persons who think that an attempt is being made to make it impossible to build a shed without the intervention of an architect and what Mr. Ireland calls "the inevitable 5 per cent." It seems also that some builders think they will no more be free to build from their own plans, but that at the first sign of building some monopolist architect will be down upon them and place his veto on the work until he is called in and gets his fee. It is no wonder that legislators who approve of the measure themselves are nevertheless timid about being associated with it. As a matter of fact, neither the Act nor the amendment do or could declare that an architect must be employed for anything. It is the architect himself upon whom it is proposed that the law should lay its hands and say what he must do; that if he wants to profess architecture he must give evidence that he is qualified to produce sound architecture. That is the whole story, and if anyone can extract from such a proposal anything but benefit to the public, or any direct benefit to the architect, or any indirect benefit to the architect which is not also a benefit to the public, he has a statement to make that has never been made before; for any objections that have been raised hitherto have been founded either upon mere anxiety or upon misapprehension of what is proposed.

In simple truth, the Act is intended to benefit not the architect, but architecture. But the architect believes that everything which raises his art will make his own life better worth living. Therefore he favors it.

PUBLICATIONS.

William Paul Gerhard, C. E., Consulting Sanitary Engineer, is the author of a book entitled, "Theatre Fires and Panics—their Cause and Prevention," the first edition of which has just been published by John Wiley & Sons, New York. Price $1.50.

We have received from the publisher, Mr. Wm. T. Comstock, 23 Warren street, New York, a copy of his Directory of Architects of the United States and Canada for the year 1896-97. An examination of the book shows the list of Canadian architects to be so full of errors, as to be of little value. The price of the directory is $1.00.

The cutting in half of the ordinary rate for weekly papers by the Montreal Weekly Gazette has been attended by a large increase in circulation, which the publishers expect to see still further expanded during the coming season. The Weekly Gazette gives all the news and interests all classes who take an intelligent interest in public affairs and the development of Canada's resources. At fifty cents a year it is the cheapest of the metropolitan weeklies, and it is good. It is published by the Gazette Printing Company, Richard White Managing Director, Montreal, to whom correspondence and orders should be addressed.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

DEFECTIVE PLUMBING.

"Property," a real estate paper published in this city, recently printed the following:—"Two cases have just been reported to us which prove the folly of getting a cheap plumber, who will turn out a job that is always unsatisfactory and sooner or later leads to further expense. In repairing the closet in a house in this city the workman happened to strike the ventilator in the ceiling with his head. It fell down with such a slight knock that the man looked at the hole and found that the ventilator was a dummy one, not going beyond the plastering of the ceiling, and of course it was not of the slightest use. In the other case, one of our leading plumbers was called in to examine some tenements where the tenants complained of bad smells and leaks. On examination he found that the soil pipes were made of galvanized iron and had naturally been rusted into holes, allowing both gas and water to escape. The whole of the houses had to be done over again, entailing double expense and a lot of trouble. Moral: Get your plumbing done by a reliable firm."

SAFETY OF FLOORS.

The City Building Inspector reports as the result of his investigations into the cause of the collapse of the building in this city in which the recent fatal fire occurred, that the falling of the upper floor was due to overloading with merchandise. The floor was so far overloaded that the additional weight imposed by the water thrown into the building by the firemen caused the supporting beams to bend and give way. The practice of loading floors of warehouses with merchandise to an unlimited extent, and without taking the precaution to enquire what load they were originally designed to bear, is far too common in all cities. The means for the prevention of accidents from this cause are provided in the draft building by-law prepared by the Province of Quebec Association of Architects, and now under consideration by the City Council, as follows:—

"The floors in all buildings hereafter erected, or floors in existing buildings which may be renewed, shall be so constructed as to carry safely the weight to which the proposed weight of the building will subject them, but the least capacity per superficial square foot exclusive of materials in floor, shall be as follows: For floors of dwellings, 70 pounds; floors of offices, 100 pounds; for places of public assembly and schools, 125; warehouses, stores, factories and buildings for other commercial purposes, 150 and upwards, according to the use for which they are intended.

"In all warehouses, storehouses, factories, workshops and stores, where heavy materials are kept or stored or machinery introduced, the weight which each floor will safely sustain upon each superficial foot thereof shall within 90 days after the passage of this act be estimated by a competent person employed by the owner or occupant.

"But if the inspector shall have cause to doubt the correctness of said estimate, he is empowered to revise and correct the same, and for the purpose of such revision he and the assistant inspectors may enter any building and remove so much of any floor or other portion thereof as may be required to make necessary measurements and examination.

"When the correct estimate of the weight the floors in any such building will safely sustain is ascertained as herein provided, the inspector shall approve the same, and thereupon the owner or occupant of said building, or any portion thereof, shall post a copy of said approved estimate in a conspicuous place on each story of the building to which it relates."

ARTS AND MANUFACTURES.

The classes in connection with the Council of Arts and Manufactures were opened a few weeks ago. The instruction is as in former years. A great number of pupils were enrolled. Mr. L. A. Boivin occupied the chair. The classes are held from 7.30 to 9.30 p.m., and are entirely free of charge. The greatest enthusiasm prevailed and everything points to a very successful season's work.

ST. JEAN BAPTISTE SOCIETY CLASSES.

The course of public lectures delivered under the auspices of the St. Jean Baptiste Society are well attended. A large number of persons have attended these lectures, and those who have not should not fail to do so in the future. It is a good way to obtain knowledge in different branches of art and science. The lectures are entirely free, the sum of $2,500 being granted every year by the Quebec Government towards the expenses. On the opening night Mr. Justice Loranger, who occupied the chair, explained that the object the society had in view was to educate the laboring classes, and that the lectures were approved by the Council of Arts and Manufactures as well as by the Council of Public Instruction. In presenting the address of welcome to Premier Flynn, the president made allusion to the advantage it would be to have a museum of mineralogy, and asked the assistance of the Province for this object. Mr. Flynn, in replying, wished the society all the success they deserve to achieve in their undertaking. The names of the different classes have already been given in the ARCHITECT AND BUILDER, the only change being that Mr. Boivin, instructor in Applied Science, has tendered his resignation on account of illness, and has been replaced by Mr. E. Lafontaine.

PERSONAL.

Mr. F. W. Guernsey, C.E., of Stratford, was recently married to Miss Rose Sharp, of that city.

Mr. Edward C. Linden, a well-known contractor of Hamilton, Ont., died at the hospital in that city last month. Deceased was 39 years of age.

Mrs. C. H. Wheeler, wife of the well-known architect of Winnipeg, died in that city on the 18th of October. Mr. Wheeler has the sympathy of many friends in his bereavement.

Mr. George Clapperton, superintendent of the Bennett & Wright Co., Toronto, was presented by the employees with a beautiful tea service, on the occasion of his recent marriage.

The friends of Mr. Alan Macdougall, C. E., will be pleased to learn that his health has been greatly benefitted by his recent stay in Great Britain. He expects to return to Toronto at the first of the new year. Mr. Macdougall was appointed to assist in making arrangements in Europe for the visit to Toronto next year of the British Association for the Advancement of Science.

Mr. Thomas Fuller, Chief Architect of the Public Works Department, Ottawa, was recently presented by the Governor-General with a souvenir, in the shape of a solid silver snuff box, the lid of which is a very finely executed bas relief of Christ blessing little children. The engraving on the lid is as follows: To Thomas Fuller, Esq., from H. E. the Earl of Aberdeen, as a small token of appreciation.

Sergt. Harp, who was one of the crack shots of this year's Wimbledon team, is a well-known Toronto contractor, having been in business in that city for ten years past. He has lately returned from Great Britain, where he won upwards of $500 in prizes, and has determined to try his fortune in British Columbia, for which province he took his departure a fortnight ago. Sergt. Harp established for himself in Toronto an excellent reputation as a contractor, and will no doubt succeed in his new field of effort.

The news of the sad death of Mr. John Day, architect, of Guelph, Ont., which occurred on the 5th inst., was learned with much regret. It is supposed that he met death by his own hands. For some years he had been suffering severely from the effects of a fall he sustained while superintending the erection of the Commercial Hotel at Guelph, and at times was quite morose. Mr. Day was the youngest son of the late Wm. Day, builder, and had a thorough knowledge of his profession.

BY THE WAY.

A TORONTO hardware firm have had in stock for several years a pair of door hinges of decorative design, which, on account of their unusual size, they found themselves unable to dispose of. A month or two ago these hinges came under the notice of an architect who had a house in course of erection in a fashionable quarter, and who saw possibilities in effect which might be achieved by their use. The hardware merchant was glad to get rid of the unsaleable articles at less than half the price he had originally put upon them. The architect designed a perfectly plain oak-veneered door, with a small opening filled with fancy glass in the upper part, and placed the hinges upon it. The effect is said to be decidedly unique as well as pleasing. By-the-bye, the builder was obliged to send this door to a piano factory to be veneered, owing to the unusual extent of surface.

× × × ×

"YOUR remarks, recently, anent the injury likely to result to the reputation of the furnace manufacturer who permits work of installation to be imperfectly carried out, were undoubtedly correct," said a manufacturer in this line to me the other day. "The speculative builder used to come to us and specify a furnace far too small for the requirements, with piping and other adjuncts in proportion his object being to sell the house as soon as possible. Formerly we were accustomed to sell what was asked for, believing that as we were to have no part in the putting in of the system, no responsibility could attach to us for its proper working. Latterly we have come to view the matter differently. When we came to consider that the occupant of a house which is thus inadequately equipped for heating, notes only the fact that the furnace bears the name of a certain manufacturer, and attributes all his discomfort to a defective heater, we were not long in concluding that our good name was in danger. Now, when a builder comes to purchase a furnace from us, we insist upon knowing all about the house in which it is to be placed, and we will refuse to sell a No. 4 furnace to do the work of a No. 7o."

ILLUSTRATIONS.

NORMAL SCHOOL, HAMILTON, ONT. WILLIAM AND WALTER STEWART, ARCHITECTS.

DIOCESAN THEOLOGICAL COLLEGE, MONTREAL, QUE.—A. T. TAYLOR, F.R.I.B.A., ARCHITECT.

HOUSE, LAVAL AVENUE, MONTREAL, FOR MRS. JOSEPH LEVY.—VIEW OF HALL IN SAME.—J. & H. C. NELSON, ARCHITECTS.

The material is red and buff sandstone and pressed brick, with red tiles on front gable and upper storey of tower. The interior finish will be chiefly of whitewood. Owing to the nature of the soil the footings of all walls are composed of concrete and light steel girders.

NOTE. In the description accompanying the illustrations of proposed bridge across the St. Lawrence river at Montreal, which recently appeared in these pages, mention should have been made of the name of Mr. Walter Shanley, consulting engineer for the Montreal Bridge Co. and referee for the award of prizes—also Mr. C. N. Armstrong, managing director of the company.

TRUE FACTOR OF SAFETY.

THE employment of the so-called factors of safety implies corresponding degrees of inexactness of our knowledge of the precise static or dynamic value of the resistances of structural materials, details and workmanship. The degree and kind of this inexactness varies, says the Contract Journal, according to the nature and purpose of the structure in question to which the factor is applied. The factor for a live or dynamic load is usually assumed to be double that for a dead or static load. When the load consists partly of static and partly of dynamic effect, the live load may be converted into the assumed equivalent dead load, and added to the dead load portion of the estimate. The factor of safety has generally reference to a fraction of the ultimate breaking or destructive strength of the materials. This gives rise to a large numerical factor. Hence there has been a tendency by the inexperienced to curtail the fractional value of the factor of safety to a rather hazardous extent. This is especially so when applied to materials and workmanship, as well as design, which are of an inferior character. The destructive strength of materials is often a very valuable ratio (say two or three times) of the crippling strength, and is still larger in excess of the elastic limit of the materials. The elastic limit, however, has likewise a somewhat variable and uncertain value with different testers, and the precision of different testing machines is not alike in degree or manner of registering the limiting point. But neither series of values, of the destructive or crippling strengths, or the elastic limit, has any constant relation the one to the other alike in all materials nor in all samples of the same materials. In good present practice the elastic limit is assumed as the basis of the factor of safety, because it is the nearest approach to the serviceable strength of all structural materials for all practical purposes, and involves the minimum of uncertainty. The factor is therefore correspondingly reduced to a half or a third of the elastic limit, according to the complexity of parts. The adaptability of the design and details, and of the character of the workmanship and materials in the several parts and positions, to the purposes of the structure must be considered. Permanence under exposure to weather or injury from other causes, or from variable or accidental loading, etc., must likewise be kept before the mind.

MORTAR OF BRICK DUST.

IT will not be without interest, says the Moniteur de la Ceramique, in a recent issue, to make a note of the application of brick dust for the making of mortar. Why not, indeed, use this substance, if it is good, and even economical in certain cases, as a substitute for cement? Experiments have been made with a mixture of this substance with quicklime, and blocks made of such composition, thirteen millimetres thick, after having remained submerged in water for four months, have sustained, it appears, without cracking or breaking, a weight of 10,500 kilograms per square decimetre. One part in ten of the brick dust was sufficient to give ordinary mortars a remarkable cohesive power. This composition was serviceable for the construction of drains, reservoirs, cisterns, the tops of terraces, etc. The best proportion is one part of brick dust, one of lime, and two of sand, the whole mixed dry and wet with the water necessary.

"ARCHITECTURE IN THE UNIVERSITY."

UNDER the above title Prof. Capper, occupant of the recently established chair of Architecture, delivered on the 5th inst., the annual University Lecture to the students of McGill University, Montreal, as follows:

Architecture is a subject which, in the older universities of Europe, as distinguished from mere technical schools, has hitherto received but scanty recognition. At Oxford and Cambridge it has been represented but fitfully. The name of Prof. Willis, of Cambridge, will recur to many; at Oxford also that of the Slade Professor of Art, John Ruskin. Both must ever be mentioned with honor. But the recognition of the subject has been solely on its theoretic and historical sides, that is, from the æsthetic and archæological standpoints. In no Scottish University is there a Chair of Architecture proper, though Edinburgh possesses a Professor of Fine Art, and Glasgow, by a curious antithesis, is endowed with a Chair of Naval Architecture. The more modern teaching bodies in England, King's College and University College, London, and in Liverpool—quite recently added to the list—the University College of the Victoria University, have ah Chairs of Architecture, both Theoretical and Practical. In France there are many local technical schools, and in the Ecole des Beaux Arts in Paris we have a great central school devoted to Architecture and its sister arts—rather would I venture to say its handmaid arts of Sculpture and Painting. But it is a so-called special school; it forms no part of the famous University of Paris; nor, so far as I know, is Architecture a university subject in Germany, Austria, Italy or Spain. In all these countries there are great technical and special schools, more or less on the model of Paris.

On this side of the Atlantic, on the other hand, in the United States, not only are there great technical schools, such as Massachusetts College of Technology at Boston, but we have a very frank University recognition of Architecture at Cornell, at Harvard also, at the University of Pennsylvania, and, above all, at Columbia College, New York.

In Canada we have at Toronto, forming part of the University, the School of Practical Science, in which Architecture is included.

To the list of those that embrace Architecture in their curricula, McGill University must now be added. The Chair has here been attached to the Faculty of Applied Science, which hitherto, with the exception of Practical Chemistry, has been wholly devoted to Engineering in its various branches. That there are peculiar advantages in this arrangement, I shall, I trust, have little difficulty in showing. I congratulate myself that Architecture is thus closely combined with Engineering, for, after all, of course engineering is for the most part but very specialized architecture, though, too often, it may be maintained, its somewhat unnatural offspring. And I venture too, by way of suggestion, to congratulate my engineering colleagues themselves, for, on the Scriptural principle that "a little leaven leaveneth the whole lump," I cannot but hope that ere long through them the salutary influence of Architecture may be felt, and may insensibly raise those engineering ideals, which, at present, with all their boasted scientific advance, have succeeded—can any one deny it?—in afflicting the world with some of the most gigantic monuments of ugliness that as yet man has ever achieved. (Laughter and applause.)

The peculiar dangers against which Faculties of Applied Science have to contend and as such I unhesitatingly class the great Faculties of Medicine, of Law, and even of Theology itself—are that the true University standard of education for the whole man be lost sight of in the eager struggle and restless activity which characterize our modern conditions of society. In the struggle—I had almost said the scuffle—of existence, the student is naturally eager to equip himself with the utmost despatch for his work in life, that is, to shorten his probation, if by any means he may start the sooner in life's race. He is apt to view with impatience all subjects that lie outside his immediate path, and to devote himself exclusively to those by mastering which he may the more quickly gain his own livelihood and feel that he is advancing apace. Such "Brodstudien," as the Germans call them, the studies whose object is the mastery of the craft by which the student is to live, are specially technical, and form the basis of the technical schools, most admirable institutions, doing admirable work for the land, but still not universities. To grasp the distinction between the technical school and the university is of importance. Speaking generally, the essential difference between the two consists, it seems to me, in this: the technical school is equipped exclusively for and aims solely at imparting the knowledge that is requisite for a man's stock-in-trade, so to speak, as a handicraftsman in the labor of life. It does not seek to do more than fit the student for conducting on approved lines and with success the business of life—whether commercial, or manufacturing, or professional. But the university aims at a higher standard of equipment and of life. Its ideal is more than a livelihood made, however successful. Its ideal is the man, quickened and developed in all the resources of his intellectual and moral being, with the avenues of knowledge opened out to him and harmoniously correlated, even though it is possible for the individual to take but one or other of these avenues for his own special walk in life. A University, if subdivided into Faculties, is yet more than any Faculty or group of Faculties; it is more than all the Faculties combined, for it is the co-ordination of them all into one harmonious whole, evenly balanced and justly interwoven to make up the great, the inexhaustible, sum of human knowledge and human activity, both intellectual and moral. It is said that universities are unpractical; that they do not fit a man for the practical business of life. It seems to me, on the contrary, that the university of to-day, properly equipped and working with modern methods on many lines, enriched by the inclusion in its curricula of all those subjects which modern life embraces and demands, is the only practical training ground for life in its fullest and noblest sense. To be educated is not to be unpractical, and with the vast increase of knowledge in almost innumerable branches that has crowded the intellectual life of modern times with rich stores undreamt of in bygone days, education is but piecemeal and stunted and one-sided that does not in the fullest measure seek to develop harmoniously the man in his entire life and being, that does not strive to widen the horizon of his knowledge, of his intelligence and of his sympathies, and that rests satisfied with an equipment, in itself it may be thorough, that is limited to the immediate needs of his own necessarily narrow calling. (Cheers).

Has Architecture then a right to a place in the university curriculum? Can it vindicate its claim to the higher recognition implied by its admission amongst the subjects of university teaching? Not only do I fearlessly claim for it that right, but I maintain that its inclusion in Applied Science is the surest way of maintaining unimpaired that true university standard of which I have spoken in the Faculty which is liable perhaps more than any other to be assimilated to the mere technical school. It is not the ideal of this Faculty—as has been scornfully or enviously suggested—to flood with the greatest possible number of the best drilled men the engineering profession in this country. The ideal of a Faculty of Applied Science in a great university is certainly to place at the disposal of those men whose bent is toward its particular subjects the highest training that modern science has to offer in those subjects, but at the same time to imbue them, as far as possible, with the broad catholicity of the university spirit, to widen their horizon with the university recognition of the unity of learning and the co-relationship of knowledge, in a word, to educate to the fullest the man, as well as to train the chemist, or the architect, or the engineer. (Applause.) And for such an ideal Architecture, I venture to affirm, with all deference to my colleagues, is of greater import than engineering. For what is Architecture? and what is its relationship to Engineering and the Arts? What, too, its relationship to the other Faculties? What has Architecture in common with the studies that constitute their curricula? Architecture is the science and art of building well. It is at once the most artistic of the sciences and the most scientific of the arts. It has been said—and no less a man than Mr. Ruskin has lent his great authority to the delusion—that the function of architecture is to ornament, that architecture is concerned with applying to a building ornament and features that in themselves are useless. No more monstrous fallacy was ever preached or swallowed wholesale by gullible humanity. Architecture is no such meretricious afterthought like the wooden Doric portico outside, which does duty for the Faculty of Arts. If it were so, the columns of the Parthenon would be hardly more respectable as art than the scalps with which the average Indian may have adorned his wigwam. Yet it is amazing how this inane idea has laid hold of men who should know better. It has met me already within the precincts of McGill (laughter); it has been held forth to me, in all seriousness, within the Applied Science building itself. (Renewed laughter).

Six thousand years ago—or more, it may be—on the edge of the desert, 150 feet above the Nile, there was raised the "most

enormous pile of building" ever reared by man. In it are combined "the finest masonry" and "the most accurate construction known." Many thousands of skilled workmen and an army of a hundred thousand unskilled laborers were employed, it is believed, in building it for twenty years. It is the sepulchral monument of a man whose name we know, but that is all. In all that colossal building, there is no shred of ornament, no vestige of enrichment of any sort; there is nothing "useless," unless it be the whole gigantic pile. For, indeed, it has tragically failed to insure, a poor inviolability to the body of its founder. Yet, that the Pyramid of Khufu is architecture on the most majestic scale, no one, I think, will deny. I, for one, will gladly add that it is also engineering, magnificent engineering, of which for scientific accuracy we moderns might be justly proud.

Architecture does not consist in mere ornament or decoration. Art is not to be measured by its uselessness, but by its use; nay its vital necessity for the adequate expression of human intelligence and activity; were it otherwise, I would most willingly concede that, in the midst of such essentially living subjects as Mechanical and Civil and Electrical and Mining Engineering, not to mention Hydraulics—all of the greatest importance in the life of our modern complex communities—Architecture would but survive as an excrescence, an effete tradition, a cumberer of the ground, with a past indeed, but hopeless of a future. Art is neither so shallow a thing, nor yet is it a mystery, a hidden secret revealed to the few and to be swallowed, like a prescription, by the many. Art for the most part is common sense. It is experience touched with poetry. (Applause.) To Michael Angelo, the great Florentine sculptor, painter, architect, engineer and poet of the 16th century, we owe the significant sentence, "I know but one art." And our modern distinction between fine arts (by which we mean mostly painting and sculpture) industrial arts and mechanical arts and applied arts is wholly a fictitious one, unsubstantial and based on nothing at all in nature or in life around us. The most artistically gifted nation there has been of the Aryan stock is the ancient Greek, whose heyday lasted but a few brief centuries. But the Greeks—like Michael Angelo—knew but one art, and that was good art—and they called it TECHNE, "skill." In the Middle Ages, too, as in the heyday of arts in Greece, this unreal discrimination between art that is fine art and art that is some other art, did not exist. "There was only one art, and that true art," whether expressed in color, as painting, in form, as sculpture, in the total of a noble building, or in the commonest objects of daily use.

I crave your indulgence for enlarging upon this topic, which some may think well-worn and even threadbare; but the extraordinary notions that prevail upon art, the mysterious way in which it is spoken of as something apart, like some religious cult, not to be judged of or understood by ordinary folk, show how misunderstood it is. Art in architecture, as in everything else, consists in that fitness and adaptation to a purpose, that appropriateness in function, in form and expression, which, I most sincerely believe, are not only inseparable from, but are the essence of, our appreciation of the beautiful.

Take a modern racing yacht and compare it with a craft of olden days—the latter is picturesque enough in hull, with poop and forecastle, in its bellying sails falling naturally into curves that please the eye. But is the modern yacht one whit less beautiful? To me it is infinitely more lovely, yet every line of hull is calculated for a purpose—speed—and every sail is stretched to suit mechanical laws. The beauty—and I know no more graceful outcome of modern scientific design—is due to fitness and absolute appropriateness; it is most truly art. Take many a modern engine—the same holds good. Can anything more perfectly express and emphasize its function and its purpose than a modern, well-designed machine? And just in proportion to this successful expression is it beautiful and truly a thing of art.

"The designing of machinery,"—to quote a recent authority—"whether for peace or war, has now reached such a high standard of excellence in function, form and expression that one is justified in saying that these things are entitled to rank as works of art as much as a painting, a piece of sculpture, or a building, and also that machinery is the only true constructive art that has been produced since the decline of mediæval architecture. . . . Do not misunderstand me by thinking that I want to raise steam-hammers and pumps to the level of a painting or a piece of sculpture. All that I maintain is that they are true works of constructive art, and ought to be recognized as such. Moreover, in conjunction with the best art of former days, they teach this important lesson, that man cannot, unless warped by bad education and false criticism, construct anything except in a natural, functional, and therefore artistic manner."

These sentences I have quoted are taken from a very admirable presidential address, delivered not by an engineer to engineers (as possibly you might suppose), but at an art congress in Edinburgh, by the most eminent of living Scottish architects. So, too, it is with architecture. Features that are mere excrescences cannot be really beautiful. A building that fulfills its purpose truthfully and well, that expresses faithfully its function in its form, will always be a satisfactory bit of architecture so far as outward design can go; while no amount of superficial ornament, however lavishly applied, can make a building really beautiful that fails in essential fitness to its purpose—that is inappropriate. Let me, however, not be misconstrued. Far be it from me to disparage ornament, when rightly used. It is against its false use, and, above all, against that total misconception that makes ornament all in all, exalting the accessory to be the essence, that I have been contending. Architecture may, as in the Pyramids, be majestic and sublime with never a trace of ornament; even ordinary building may depend solely for its effect on proportion and appropriateness, and be true art. But for the most part architecture craves for ampler expression, and in ornament, not applied from without but logically evolved from within, the outcome of the building in organic growth not added as an afterthought, we find the readiest and truest expression of the architect's design. The Parthenon is still an unrivalled monument of grace and dignity, though its sculptures for the most part are torn from it and scattered in museums. But it was when its true and noble architecture was completed with and wedded to its glorious ornament and sculpture, as one complete organic whole, that this most incomparable work of Grecian art was consummated. For Architecture does at least recognize that it should be beautiful. And herein, I venture to think, lies its superiority as a university subject to Engineering, in that it is more true to our wider human nature. Constructive engineering, as I judge of it, means, under present conditions, construction reduced to mathematics. It is building by calculation solely, with the result too often of a skeleton without the life. It is economy not only reduced to science but exalted for our worship; it is the apotheosis of utility. But man, in the long run, craves for what is permanently beautiful, while the modern engineer too often seems wilfully to make for what is ugly. Just as the German scientific writer of to-day apparently thinks that a lucid literary style is a pandering to what is popular, and therefore clothes his thought in those Teutonic periods so fearfully and wonderfully made—ingens, informe, cui lumen ademptum—so, too, the modern engineer seems to think that any attempt to make his structures beautiful is waste, a pandering to mere architectural effect, unworthy of scientific designing. Ultimately, I cannot but think, he will find that he is wrong; frail human nature, I believe, will rise in revolt against what is intolerably ugly; and I have too much faith in the engineering profession not to feel confidence that in the long run their great achievements will be brought to harmonize with this human need and will be beautiful without being one whit less scientific.

On the other hand Engineering scoffs at Architecture—and, I frankly admit, in many cases with much reason—for its faulty construction and its haphazard methods, not to speak of its frequent and most lamentable failures to be appropriate and beautiful. That Architecture ventures on criticizing Engineering I have possibly shown; that it fails to justify itself too often, that it is not beautiful, I must sorrowfully admit. Only in the due co-operation of these two great branches of construction, only by loyally accepting each other and working in harmony together, can we, I believe, achieve in these later days the best results. And it is with no ordinary feelings of satisfaction and hope that I enter upon the work of the teaching of Architecture in McGill University, where in the Faculty of Applied Science to a greater extent than in any other university with which I am acquainted, these two departments are knit together, working side by side, so as to acknowledge and appreciate and supplement each other. (Applause).

But the scope of Architecture is wider yet. Not only must it be scientific to be genuine and therefore allied to, nay, much indebted to, the accuracy, the refinement in calculation and the certainty of engineering; not only must it be artistic to be true, and therefore at once the foundation of all the arts and essentially an all-embracing art, if the term is to have real meaning; but it is a many-sided study. Hydra-headed, the student is tempted to feel, when the examination-hall looms near—related to

life on many sides, and of a very special and intimate kinship with many—I might almost say with most—of the studies included in the university curricula.

Take, for example, Medicine and Law. In the former the great department of Hygiene is as much architectural as medical; and rightly to understand this branch of science, so important to us all, individually and as communities, some knowledge of scientific planning and building, of sanitation and of plumbing, should be as necessary to the Bachelor of Medicine as is, without doubt, essential to the architect some acquaintance with bacteriology and germ theories, with the spread and prevention of diseases. The two studies, apparently so far apart, have this much at least absolutely in common, and upon common ground like this, the unity of learning receives a very patent application.

So too in Law, where Professional Practice of the architect, Contracts and Arbitration, are the common ground, much as Medical Jurisprudence is common ground to Law and Medicine.

Even in Theology and Divinity again, it is obvious that we have common ground. It is not that I claim it necessary for an architect to be a theologian—heaven forbid; but who can look back upon the grandest triumphs of Christian architecture, those glorious cathedrals, in which are enshrined the piety and devotion and zeal and faith of the middle ages, without feeling that the men who planned and built those temples were in truest sympathy with the creed for which they built them. A little further back and the monk who worshipped in the Abbey church and the monk who built the Abbey church were brethren in the self-same cloister. And even in these modern days, when work is specialized, and students of architecture and theology have perforce their separate schools of study both, it may be, apt to be too technical—that architect, it seems to me, cannot be of the highest sort who in studying a church is wholly indifferent to the forms of creed and worship of which he seeks to understand the outward shrine. (Applause.)

In the Faculty of Arts—that faculty to which all of us who have had the immense advantage of attending its courses (whether in this university or elsewhere) must ever look back with deepest gratitude and most loyal affection—gratitude for its broad, true education in the fullest sense, for its humanizing influence on all our after lives, for its catholic, vitalizing inspiration that does not pass away—affection for its serene disinterested ideals, which we fain would cling to through storm and stress of after years, yet cannot always keep before us as we would—in the Faculty of Arts there is scarcely a subject, I am thankful to claim, with which Architecture has not close and abiding kinship.

To Philosophy we turn in relationship of pupils to our teacher. Where else can we get the principles of logic, of induction and deduction, that must be employed in criticism? Where else the foundation for those principles of æsthetic sense and art, which it is ours to embody in creating logical, harmonious design?

To Architecture, as to Engineering, Science is of vital import—the foundation upon which it works, from mathematics to geology, from botany and chemistry to physics. Where else can we get the principles of statics and dynamics, of thrust and equilibrium, arch and buttress? Where else can we learn to know the materials that we are using? For, not knowing them, how can we hope to use them aright? Where else can we learn the principles—the despair of architects—of sound and heat and light, to apply which in actual buildings as acoustics or as ventilation is so often, even to the best of us, a source of tribulation, discredit and disaster. (Laughter and applause.)

With Literature and Classics it is obvious that Architecture goes hand in hand. Our modern architecture is as steeped in classical form and classical tradition as is the language we speak and use from day to day. Does not the exquisite harmony and proportion of Greek architecture, even in its ruins, form the truest, the most vivid illustration of that Hellenic spirit, which still profoundly rules mankind? Is not the oratory of Demosthenes brought home to us by the rhythm of the Parthenon, the music of Æschylus and Sophocles and Plato, by the beauty of Doric Propylæa or Ionic Erechtheum? Does not the might of Rome, welding the civilized world for the first time in its history into one great empire, impressing a sense of unity like a revelation, on the world, so that after centuries, right down to our own, still clung to it and strove to realize it as of old—does Rome not find its expression as truly in its architecture as in its laws? that architecture, which still maintains its hold upon us, and which twelve or thirteen centuries ago was planted by the conquering legions triumphantly from East to West, from far Palmyra to Eboracum in Northern Britain. Roman building is indelibly stamped with the imprint of the Roman character and genius; from the Atlantic to the Euphrates, from Wroxeter in the west of England, or Lincoln in the east, to Nimes in France, or Merida in Spain, on the Tagus, the Tiber, or the Danube, in Asia as in Europe, her architecture, ruined and fragmentary, as it mostly is, still bears the most eloquent of testimony to the vigorous, pre-eminent, unifying power of Rome; it is the grandest illustration the Latin classics could desire. (Cheers.)

If there is one subject in the Faculty of Arts that seems to appeal to all with (varying, perhaps, but) never failing force, whose educative value (it seems to me) is inexhaustible, its human interest perennial, it is the study of history. My colleague, whose occupancy of the Chair of History at this university is a cause for rejoicing to us all, (applause) will not, at least, gainsay me, when I claim that there is not a more convincing commentary on the history of the past than the architecture which that past has bequeathed us. Architecture is the most obvious, the most obtrusive of the arts; it confronts us in our homes and in our streets; wherever we travel in countries which inherit the precious legacy of history, the great monuments of architecture are second only in interest and importance to the great landmarks of nature herself. They are noble records of the past in stone. Wherever man has dwelt and lived worthily, he has left, heaped up in noble piles, the history of his day, the memorial of the deeds he did.

Architecture is the great "object lesson" of history. Without its eloquence of storied stone, history would be shorn of its most poetic, its most impressive and oftentimes its only witness; it would sink to the dull prose of the half forgotten chronicler. It is, perhaps, through its buildings mainly that the past holds out in tangible form its living hand to the present. What other link have we at once so impressive and so human to bind us to our forefathers? to connect the life of to-day with the life of bygone centuries? to remind us that to-day, with its struggles and weariness, its whirl and strife, its success and its disappointment, is yet not all; that centuries and centuries have come and gone in which men have lived and striven and struggled too, have lost and won, and have handed on the torch to the next runners in life's handicap. (Applause.) Voltaire, I think it was, but the phrase has been so often quoted that by whom first said is half forgotten—Voltaire has said: "Happy the nation that has no history." Whoever it was that said it, he spoke a most preposterous folly. It is not even a half truth, in the sense that a nation's history must register a nation's crimes. A Hottentot has scarcely a yesterday or a to-morrow. That is to be without a history, but it is not to be destitute of crime; nor is it national happiness. And, need I remind you, the Hottentot has not evolved an architecture; he lives on in ignoble generations, till ultimately, inevitably, and perhaps properly, snuffed out. A nation that has no history is not a nation; and every nation that has the incomparable blessing of a history has something at least to show in the way of its national architecture. In a very special way architecture is concerned in the ennobling legacy of the past: only through the past can we builders learn thoroughly to grasp the present and work out strenuously the future of our craft.

With an illustration or two of History in Architecture, I have done. First, let us glance at Ancient Egypt—comparatively a morsel of a country, consisting of the oozy Nile bed, and corresponding very closely with Euclid's definition of a line—length without breadth. In this narrow strip of country, long drawn out, a people not so very numerous, have contrived to write their history in architecture in characters so magnificent for scale that for sixty centuries they have been unrivalled. Only from the overpowering architecture of their tombs do we know those mighty men of old, the builders of the Pyramids. Yet their names are imperishably preserved for us in the majesty of their violated limestone shrouds. They are happy in that their architecture has kept for us their history; a history that remains forever fresh, from the ineffaceable impressiveness and grandeur of their works.

Or take, some five and twenty centuries later, their distant successors, the Kings of Thebes. Can the memory of Rameses ever pass away so long as his ruined halls at Kanak and Luxor—those mightiest of temples—remain to tell their wondrous tale? Year by year that wondrous country of the Nile yields up to modern research that wearies not the secret of its centuries so long by-gone; will the fascination of Egypt ever grow dim? Will the romance of its history grow stale and unprofitable to us moderns? I cannot think it. But where would that history be if it was not for those incomparable monuments in which it is enshrined? Perhaps nowhere else on the face of the earth are the history of a people and its architecture so absolutely synonymous.

Let us turn to early mediæval Europe, those countries of savage

hordes slowly rising into civilization amidst the ruins of Rome's vanished might. The history of the tenth, the eleventh, the twelth and the thirteenth centuries is written for us in the monkish chronicles—which are dull reading in all conscience. But infinitely more impressive and more vivid is the history written for us by those self-same monks in stone and lime, history which it is a fascination to spell out among the crumbling ruins of their buildings, so lovely in their decay. The chronicles in great part are occupied in dwelling for edification upon the rather foolish miracles in which the patron saints indulged; it seems pitiful, and childish and infinitely wearisome to us now. But the ruined church and cloister show us what they did, these monks, who were neither fools nor children when it came to action, in the centuries when they had work to do and did it. William the Conqueror in England, to establish his throne securely, harried with incredible cruelty and fury perhaps the fairest province in his dominions. From the awful severity of that blow, so swift and pitiless and thorough, Yorkshire and the north lay prostrate, too drenched in blood and ruined to recover life. Who and what saved that desolated land and made it once more populous with thriving industry and fertile? Who drained the marshes, cleared the forests, reclaimed the land and turned the desert into gardens? The history of that great social revolution is written for us in the decaying walls of those Cistercian abbeys, once so fair, and still so fair, though well nigh swept away by the hand of time and the much more ruthless hand of man, which dot the vales of Yorkshire in numbers that surprise the modern tourist. There is no fairer page of peaceful history than this conquest for civilization by the monks of a whole district, and nowhere can that page be read in fairer lettering than in the ruins of the noble piles they raised while their strenuousness was still upon them.

In the 13th century France awoke from the despondency and blight of the English sovereignty, and under Philip Augustus and St. Louis found herself a nation, with her cities rich and flourishing. The history of that time, fraught with such consequence for Europe, is to be found in and illustrated by the civic charters and incorporations, but as reading it is dry as dust. These musty records cannot appeal to us or bring home to us in even the meagrest way that stirring time as do those glorious cathedrals which the cities raised in generous rivalry and with such amazing zeal, those gothic buildings without equal, unapproachable, which make the North of France to this day perhaps the richest field of architectural study in the world.

If there is one spot in England endeared and sacred to all English speaking folk, one spot in which the whole history of the Anglo-Saxon race seems summed up and vivified, reaching to our very hearts and throbbing to the very fibres of our being, is it not within that hallowed building, perhaps the most beautiful church of Christendom, which Henry the Third and his successors raised to replace the older church of the last Saxon King of England, built amid the marshes of the Thames, the Benedictine Abbey Church of Westminster? For well nigh eight centuries and a half—if not for longer the people and the sovereigns of England have worked together to make that noble church a shrine for the nation's history. I confess the great past is borne in upon me each time I linger about that nave and aisle and cloister, so wondrous in their beauty, with an almost overpowering presence. Happy—thrice happy—is the nation that has a history, and a history enshrined in such a building.

I have tried—however imperfectly—to show something of what architecture ought to aim at, something of its ideals and of the bearings of the subject in a university such as this. If it be vouchsafed to me, even in but humble measure, to impart something of the inspiration of these ideals to those whom it is my privilege to call my students, I shall assuredly feel that in dedicating such powers as I possess to McGill University, I shall not wholly be laboring in vain. (Great cheering.).

On the motion of Sir William Dawson, seconded by Prof. Bovey, a hearty vote of thanks was accorded the lecturer for his able effort.

There are few businesses that permit of greater waste in small matters, relating both to time and material, than in repairing work. A contract is often taken that, if executed in a business-like manner, would yield fair profit, but that, when actually carried out, brings almost a loss because of pure carelessness. Some workmen seem specially adapted to doing repairing work and will get over the ground in half the time of another man. Success is often brought about by carefully selecting men who show ability in some particular direction.

MARBLE IN NOVA SCOTIA.

Under this heading Mr. Geo. C. Underhill writes to our Chicago contemporary, Stone, as follows: Some thirty years ago a company was organized in Halifax to develop a marble property at Marble Mountain, Cape Breton. A better outcropping or more favorable environments could hardly be asked for. At a point on Bras D'or Lake (salt water and connected with the Atlantic Ocean) about fifteen miles from West Bay, this marble stratum crops out literally on the lake shore and is exposed several hundred feet in width, and following its course back at a right angle from the water's edge we find it for a long distance coursing vertically through a table-land perhaps two hundred feet above the water. This mesa breaks off gradually to the lake shore, making it possible to lower the marble by its own weight down to the vessels for water transportation to every coast, city and town on the Atlantic seaboard and to Europe; moreover, every large market in Canada is accessible by water direct. This marble is in good variety, white, variegated, blue, etc., and the best grades are fine, firm, and in every way desirable, while the coarser layers are A1 for building material. As might be expected, the prominently exposed points are crackled and broken, but largely by influences that obtain at the surface only, as of expansion and contraction. In a word, we have here an endless quantity, good variety and quality, cheap transportation, cheap fuel (coal at less than $2 per ton), cheap labor, and so far as Canada is concerned, a protected market; in fact, doubly so, by reason of a high import tariff and absolutely no home competition, there being no marble produced in the Dominion. I repeat, there was a company formed many years ago to work this property, and with a cash capital that should have made it prosper; but it did not. Why? Simply because the manager set out, through the means of several expensive tunnels, to reach the sound material that was not apparent at the surface, evidently not knowing why it blistered at the exposures, hence not realizing its limited extent. Just how he purposed to proceed after finding sound rock, or how perfect stone was to be reached by blasting the material into fragments in advance, is not plain. Anyhow, he not only blasted the marble but the "great expectations" of his friends as well.

Then came a long sleep for the embryo marble enterprise until in the early spring of 1894, when Mr. Geo. Hattie, a fine old Scotch gentleman, and one of the original owners, succeeded with other Halifaxians in making a second start. Again they move off with ample means and with some of the strongest men in Nova Scotia interested, among them several bank men, Prof. Fraser, who is one of the ablest men the writer has ever met, and several of the best business men of Halifax, including Roderick McDonald, the company's first president. This party has started right, beginning at the mesa's crest with channeling machines and derricks. They have gone down to measurably sound stock, and now have a mill in operation, the whole plant being under the care of Mr. D. Maclachlin, who, by the way, was one of the energetic men who aided Mr. Hattie in securing capital with which to strike the rocks of Marble Mountain once more. What the future has in store for my good friends in Nova Scotia I do not know, but this much is true they ought to win, and while there is change in everything, I believe they will prosper, for they have the wind and the waves in their favor.

CUTTING STONE WITH WIRE ROPE.

Those who have indulged in deep sea fishing know how the fish line cuts deeply into the hard wood of the gunwale as it is hauled in while taut. Even an iron protection, after a time, shows the wear of the rope, which is comparatively soft. This, says an exchange, gives the clue to an invention of an Albany quarryman for cutting stone. Instead, however, of hemp, he proposes to use wire rope, and with this he will carve the marble and stone right out of its native bed. The wire is wound in strands and has a very rough surface, powerful machinery gives a strong and steady strain, and the stone, yielding to the constant wear, parts, with smooth edges. It would be easy enough to cut the blocks after they are removed from the quarry, but where the cleverness of the inventor comes in is in devising mechanism that can be applied to the stone while in the quarry. This is effected by sinking two parallel channels in the quarry to a depth of little greater than that of the lowest level of the stone to be cut. The channels may be from 20 to 100 feet, or more, apart. At the bottom of each is made a small hole to receive the foot ends of the shatts of the machine. This is the only preparation of the quarry that is necessary. The ropes, which are coiled on huge drums, are then passed around the channels, and as the drums revolve the cutting proceeds. Suitable brakes are provided for the regulation of the speed and pressure. The ordinary speed of the strand is 800 feet a minute, so that a mile length of it passes in six minutes. While the strand is moving, crushed stone or chilled shot and water can be introduced to increase the attrition. Far better, however, than either of these is a composition obtained from the tailings of a magnetic iron separator, which costs about one-tenth as much as the chilled shot. It does not leave the lines caused by the shot, and it can be used over and over again.

ITALIAN BRICKWORK.

The late Mr. Street, a great authority upon Italian brickwork, points out in his work on "Brick and Marble Architecture" to what a great extent red brick is used with stone. Italian bricks are rather larger than ours, but not of better quality; the joints are wide, generally not less than half-an-inch. The bricks used for windows, doorways, and other ornamental features, are of finer quality and moulding.

Those who know Italian examples of brick arches and tracery are aware that the cusping of arches is of brick, set in the same radiating lines as an arch, and cut and rubbed to the outline required. He says, "In nearly all cases where brick is used for tracery, it is in the shape of plate tracery. The tympanum of the arch is filled in with a mass of brickwork, through which are pierced the arches over the several lights of the window, and these are supported on marble or stone shafts, with carved capitals instead of monials; and above these sometimes, as in the windows at St. Andrea, Mantua, are three cusped circles, sometimes only one; or else, as in the cathedral at Cremona, the plain black tympanum is relieved by the introduction of a panel of terra cotta bearing the cross on a shield, whilst round its outer circumference delicately treated, though large cusping, defines the outline of the arch." Outside the arch sometimes a red brick label 2½ inches wide is introduced. In Mantua and Asti these narrow bricks are set between rings of brick and stone youssoirs.

EARLY ENGLISH BRICKWORK.

The Eastern Counties are remarkable for some excellent specimens of early English brickwork. Little Wenham Hall, Suffolk, built in the latter part of the 13th century, shows different sizes of bricks; these are mixed with stone and flint in parts. The bricks are of Flemish shape, though some resemble Roman bricks or tiles, and the color varies. In many examples of English brickwork flint is introduced in the form of panels, and this kind of walling is known as "flush work." Nearly every important church is of this mixture of brick, or of stone and flint. Layer Marney Hall, Essex, is a noted example of brickwork. The great gate-house of three storeys, flanked by octagonal turrets, with battlements and parapets, and window mullions, exhibit an advanced stage of brickmaking and workmanship. Respecting the size of English bricks, those of Little Wenham Hall measure 9¾ inches in length by 4¾ inches wide, and 2¼ inches thick. Those made in Edward II.'s time measure 10 and 12 inches long by 5 and 6 inches wide. The "great brick" of 1734 measured 12 inches long, 6 inches wide and 3 inches thick. Portions of Hampton Court Palace show some beautiful examples of English brickwork, although a process of washing which was recently undertaken does not increase the charm of the building.

INCREASING THE RESISTANCE TO FIRE OF WROUGHT IRON PILLARS.

The following are the general conclusions arrived at by a commission appointed by the Hamburg Senate to examine and report upon the resistance to fire offered by wrought iron pillars used in construction: They withstand fire very imperfectly, their stability being quite destroyed at a temperature of about 600° Cent., and the advantage of filling them with concrete is so slight as to be scarcely worthy of consideration. The case is, however, far different with outer coatings of refractory or non-conducting materials, which have proved capable of protecting the metal from a dangerously high temperature during a certain space of time, and, consequently, of affording effective protection against fire. The substances which appear to have exerted the best effect are the cork composition of Herren T. Ganzweig and Hartmann, and xylotile encased in sheet iron, which substances give out inflammable gases for two hours and a half, leaving a carbonaceous residue that is not destroyed by the steam from the fire hose. A pillar thus coated only gives way after being exposed to the fire for four hours, while seventeen minutes suffice to destroy it if uncoated when similarly heated. Next to the above named substances comes the Monier concrete, laid on in a coat of 40 mm. (1½ inch) thickness, which preserves iron for nearly two years and a half, while plaster of Paris and asbestos cement only give poor results.—Journal of the Society of Arts.

Papyrolith Floors. According to Cosmos, floors are now being put down at Chemnitz, Saxony, which are non-conductive of heat, have no joints, and do not resound under the foot. They are made of a mass of paper reduced to powder, which, when melted with water, becomes a paste like plaster of Paris, and may take the place of artificial stone, cement concrete or parquetry, being all in one piece and polished.

THE BUILDER

[THIS DEPARTMENT IS DESIGNED TO FURNISH INFORMATION SUITED TO THE REQUIREMENTS OF THE BUILDING TRADES. READERS ARE INVITED TO ASSIST IN MAKING IT AS HELPFUL AS POSSIBLE BY CONTRIBUTING OF THEIR EXPERIENCE, AND BY ASKING FOR PARTICULAR INFORMATION WHICH THEY MAY AT ANY TIME REQUIRE.]

A Few Handy Rules.

In estimating material for a building, it often happens that no convenient means are at hand, whereby the length of rafters may be found without going through the clumsy rules of square root. In the first place, a thorough understanding of what is meant by "pitch" is necessary. The word, as used by builders, means the height of the roof above the wall plates; thus, a building 24 feet wide, having its roof ridge raised 6 feet above the wall plates, is said to be quarter pitch; if the ridge is 12 feet above the level of the wall plates, then it is said to be half pitch, etc., etc. By the accompanying rule we can get the lengths of the rafters for any of the pitches herewith named, for estimating purposes, by simply multiplying the width of the building by the corresponding decimals for the difference in pitch, which gives the length of the rafters in feet, and a decimal of a foot; multiplying this decimal by 12, we have the inches. This method, of course, is only intended to be used in figuring up the quantity of materials required; it does not give angles or cuts; these, along with the exact lengths, are better found by using the steel square, in a manner that we will describe in a subsequent issue:

RULE.

For	¼	pitch, multiply width of building by			.56
"	⅓	"	"	"	.6
"	5-12	"	"	"	.65
"	½	"	"	"	.71
"	⅝	"	"	"	.8
"	¾	"	"	"	.9

As an example, let us suppose a building 26 ft. wide, the roof to be one-half pitch, as per rule. We proceed as follows:

Width of building, 26 feet.
Multiple for half pitch, as per rule, .71

26
182

Total, 18.46
If we multiply the decimal by 12

we get 92
46

We have in inches, 5.52

or a total length of rafter of 18 feet 5.52 inches, or for estimating purposes, 18 feet 6 inches. Now this is an odd length, and would be difficult to find in any lumber yard in Canada or the United States, and to take the next regular commercial length of 20 feet, would mean a great waste of material, unless the length would be called for as lookouts over the eave, but, if 18 feet 6 inches should represent the exact length, the estimator would be justified in lowering the roof a trifle so that stuff 18 feet long would answer the purpose, and we are sure no reasonable architect would object, unless there were greater reasons than usual for the ridge standing that particular height.

Cisterns.

There is no more useful convenience to a village or country house than a good cistern, and the carpenter or bricklayer is frequently called upon to devise or construct one of these important affairs. It matters not whether a cistern is formed by simply digging a hole in the ground, without further backing, or is lined up with stones or bricks, it should be plastered with good cement, and the bricks and stones should also be laid in cement, as it makes much better work. If the ground is of a kind that will admit of plastering on, a good coat of cement may be all that is required to make it water-tight. Sand and gravel thus cemented stand fairly well, but it is better when a trifling extra expense is no object, to have the bottom and sides of the cistern lined up with either stones or good hard bricks. Clinkers are the best for cistern building, as they do not soften and crumble on the outside. Stone does very well for lining, but being heavier than bricks and irregular in size, it does not generally break joints very well, and is apt to settle and crack the cement; and being rough and uneven on the face, requires more cement to cover it, than would the same surface if made of bricks. When the latter can be obtained at from $7 to $8 per thousand, of the proper hardness, it is more economical to use them than to make use of the cheapest kind of stone-work. Usually the lining of cisterns with bricks is done by making them all "stretchers," which makes the wall four inches thick only. We think a much better job is secured by using "headers" for every fifth course; it makes the wall so much stronger and better. The bottom should be laid with bricks on edge, and should be "pot-bottomed," or lower in the centre than at the circumference. The mortar used for plastering should be formed of one part of cement and two of sand, if the cement is extra quality of the Owen Sound brand, or one of cement and one of sand if of inferior grade. Good sharp sand should be used in any case. Two coats are generally applied, and sometimes three, waiting for each coat to partially set before applying the next. The last coat should be brushed down with a wet brush while it is green, which materially assists in hardening the cement. Every cistern should be provided with an overflow water pipe, leading to some point where the surplus water may get away without inconveniencing anything. This pipe may be fixed near the top of the cistern on a level

where the water will rise to when the cistern is sufficiently full. It is also desirable to have a filter attached, in order that the water may be used for culinary purposes if desired. Filters may be attached in different ways: They are sometimes fixed at the top where the the water is let in, and sometimes they consist of partition walls, which divide the cisterns in two compartments, the water being let into one compartment and taken out of the other, holes being left at the bottom for the water to pass through the partition. Gravel, sand and charcoal, or marble chippings and charcoal, are employed to form the filter. These are filled in in layers, to a height above the holes in the partition on the side in which the water is admitted. The partition should be plastered just the same as the walls of the cistern. Sometimes a single brick partition is left between the two compartments without cement on either side, and without holes at the bottom, but the joints must be laid in cement. The water is then left to percolate through the bricks as best it may. For a time this makes a splendid filter, but after a while the pores get filled up and as a filter it becomes comparatively useless. Another filter may be made by forming a small arched mound of brickwork about a foot high on the bottom of the cistern at the lowest part. The pump-pipe is cemented into the top of the hollow mound, and small holes are left around the bottom for the water to pass through. A circular brick wall is built around the mound, about three or four inches from it and about three or four courses high, and the space between the circular wall and the mound is filled with the filtering materials, which are put in in layers. The first and last layers should be clean gravel, marble chips or spalls of other stones. The second layer of charcoal should be powdered and packed in solid. The whole of the cistern should be plastered before the filtering materials are put in place. When repairing a cistern when the cement is cracked, the cement should be cut away two or three inches from the defect, and the wall should be well wetted before the new cement is applied. The usual form of cisterns is cylindrical, and we annex a table giving contents of cisterns having that form, and of various dimensions. Cisterns having arched tops or scooped bottoms, one-third of the height of such arch or scoop should be added. The table is nearly correct and is easily understood, and will prove useful in preparing estimates for cisterns. For every foot in depth a cistern will contain:

If 3	feet in diameter	.....	55¼	gallons.
" 3½	"	"	75	"
" 4	"	"	98	"
" 4½	"	"	124¼	"
" 5	"	"	153¼	"
" 5½	"	"	185½	"
" 6	"	"	220¾	"
" 7	"	"	300½	"
" 8	"	"	392½	"
" 9	"	"	497	"
" 10	"	"	613½	"

One gallon is required by law to contain eight pounds of pure water. To get nearly the exact contents of a cistern from the foregoing table, multiply the figure opposite the diameter by the depth in feet, and you have the number of gallons the cistern will hold, nearly. For example, take a cistern four feet diameter and six feet deep, then we have: $4 \times 98 = 392$ gallons; that is, a cistern four feet in diameter and six feet deep, will hold 392 gallons, nearly.

Warm Floors.

One of the reasons why floors in frame buildings are cold, is because, when joists are placed in position, the spaces between them at the walls are left without anything to prevent cold from the outer skin of the wall from getting at will between the ceiling and the floors. In all cases, the spaces between the joists or the walls should be lathed, and a strong coat of well haired mortar applied before the ceilings are lathed. This precaution would make a house 15 or 20 per cent. warmer than where it is neglected. In lower floors this method of dealing with the spaces, or some similar one, should never be overlooked or cold feet will be the rule with those who are obliged to remain over them for any length of time in the winter. A good way to avoid cold in a lower floor if the joists rest on a stone foundation, is to "brick-fill" between joists to a level with the floors, making the "brick-filling" not less than four inches thick, having the bricks laid in good mortar and well "flushed" up to the joists and made level with the top of the timbers. In brick or stone buildings, "brick-filling" is generally done on the lower floor, but often in the upper stories where the walls are left thinner by set-backs, the joists rest on the steps formed by the set-back, and in many cases nothing is done to the wall between the joists, and the ceiling and floors are finished with nothing to prevent the cold penetrating through the thin walls to the spaces between the lath and the floor. Sometimes a careful workman will see that the brick walls between the joists are rendered with a heavy coat of mortar, which is very good in its way, and would be better if the furring ran down to the ledge or step, and the space lathed and plastered, but this is perhaps objectionable because of its forming places where mice or other vermin would find resting places. The better way is to brick-fill, leaving a hollow space between the wall and the filling, and rendering the filling on the room-side. If the projection of brickwork receiving the joists is not more than four inches, the brick-filling may overhang the walls an inch or so on the inside, so as to give a one-inch hollow space between the wall and the filling. As this projection would be between the joists it would be hidden from sight.

Steam Heating.

Of late years there have been introduced into Canadian homes a variety of heaters, including hot air, hot water, combinations of hot air and hot water, and steam heating pure and simple. In fact, there is scarcely a village, hamlet, or "corner" in the whole country that cannot boast of a "heater" of some kind, and each kind has got its own friends and admirers, all of which is right, for when a man is satisfied with anything he possesses, we take it that it would be almost sinful to unseat his satisfaction. In speaking of heaters, we do not mean stoves, nor yet fireplaces, but of some central arrangement from which heat may be projected to rooms some distance from the one containing the apparatus in which the heat is generated. Of such is the steam heater, and while this may not be the best for ordinary dwelling houses, it has become so well understood, and during the past few years has made such a rapid advance in public favor, that it seems almost unnecessary to describe its superiority over other modes of heating for large buildings, such as stores, hotels, or other buildings of more than ordinary dimensions. While it has not

V.8-9
Canadian
Archi

yet been decided beyond a peradventure what mode of heating is the most economical, it has become a fixed fact in the minds of many who have investigated the various methods, that steam heating, if the appliances are modern and fitted up with modern attachments, is by far the easiest to handle, and the desired results are more direct and rapid than the like results of any other method. Notwithstanding the fact that heating by steam is the proper thing to introduce into large buildings, we do not approve of it for use in private dwellings or cottages, unless, of course, the buildings are large and contain a great many rooms and halls. For the smaller buildings a hot water system is by far the best, and country builders, when asked by their employers as they often are what system of heating is best to adopt for warming the building they are about to erect, should advise accordingly. If the building is of moderate size and does not contain more than 16 or 20 rooms, including halls, advise hot water. If there are more than twenty and the rooms are large, then advise steam by all means. Of course, there will be other things to consider. A hot water furnace must have a place under the main floor in order that the cooled water may return to the boiler by gravitation; so also must a steam heater, for it must be remembered that the water level in the boiler must be below the lowest point of the lowest radiator. As a rule, it costs a little more to put in a hot water system than to put in steam, but when once in, and in good working order, and properly protected, it is the best device in existence for warming Canadian homes of moderate dimensions. In small houses, where the expense of a hot water system would be too great, a hot air or combination furnace will be found to be a great improvement over stoves.

PRODUCTION OF BUILDING MATERIALS.

THE fifth annual report of Mr. Archibald Blue, Director of the Ontario Bureau of Mines, which covers the year 1895, furnishes some interesting, although not altogether encouraging statistics relative to the production of building materials within the last five years. The depression in building according to the statistics, seems not to have affected the production of materials until last year, when in nearly every line there was a marked decrease in the quantity manufactured. This is accounted for, no doubt, by the fact that much of the products of the former years remained unutilized, and manufacturers were averse to accumulating further supplies. The following table gives the value of building stone, rubble and other products of the quarry for the five years, together with the amount of wages paid for labor; and shows a steady decline since 1891. For each of the last two years the value is only about one-half of the value for that year:

Year.	Value.	Wages.
1891.....	$1,000,000	$520,000
1892.....	880,000	730,000
1893.....	721,000	464,000
1894.....	554,370	336,000
1895.....	438,000	296,000

The production of common brick was greater in 1892 than in the previous year, but since that time has become less each year. The returns indicate that many of the brick yards have not been in operation. The quantity of drain tile manufactured increased from 7,500,000 in 1891 to 25,000,000 in 1894, but dropped to 14,000,000 in 1895, which amount, however, was nearly double the output of 1891. Great quantities of tile are now being used by farmers in an effort to improve their farms and to meet the competition so keenly felt. The production of common brick and tile from 1891 to 1895 was as follows:

Year.	Brick No. of M.	Value.	Tile No. of M.	Value.	Wages.
		$		$	$
1891.....	160,000	950,000	7,500	90,000	432,000
1892.....	175,000	980,000	10,000	100,000	445,000
1893.....	162,350	932,500	17,300	190,000	451,000
1894.....	131,500	690,000	25,000	280,000	388,000
1895.....	126,245	705,000	14,330	157,000	304,000

With respect to pressed brick, roofing tile and terra cotta, the largest production was in the year 1894, when it amounted in value to $286,230. For the past four years the quantity shows no great variation, and would seem to indicate two facts, viz., that pressed brick is meeting with more general favor, and that the United States product is likely to be entirely shut out of the Canadian market. The first pressed brick was made in Ontario eight or ten years ago. Below are the statistics for pressed brick, roofing tile, and terra cotta:

	1895.	1894.	1893.	1892.	1891.
Number	17,940,867	25,456,000	21,634,000	22,048,000	13,617,909
Value..	$ 184,550	$ 286,230	$ 217,373	$ 259,335	$ 156,699
Wages..	69,442	95,400	80,686	88,865	58,000

The returns relating to lime show that the production for the past five years has not varied greatly. The figures are:

Year.	Bushels.	Value.	Wages.
1891	2,350,000	$ 300,000	$ 110,000
1892	2,600,000	350,000	120,000
1893	2,700,000	364,000	122,500
1894	2,150,000	280,000	108,000
1895	2,099,000	280,000	104,000

Greater development has taken place in the cement industry than in any other line connected with the building materials, yet the quantity of Portland manufactured is less than one-half that which is imported. The production of natural cement, as the accompanying table shows, has remained nearly stationary since 1891, but the quantity of Portland has been nearly doubled. The demand for that variety for street construction, as well as for Government works, has no doubt encouraged this industry at home.

	Natural Rock Cement.		Portland Cement.	
	1895.	1894.	1895.	1894.
Number of works....	5	5	2	3
Number of workmen	45	63	129	105
Wages for labor.....	$14,166	$13,020	$46,000	$31,858
Product, bbl	55,219	55,323	58,699	30,580
Value	$43,145	$48,774	$114,332	$61,060

The following table shows the quantity and value of Portland cement imported for home consumption for the nine fiscal years ending June, 1895, and does not include any importations for Government use:

Year.	Barrels.	Value.
1886-7	102,450	$148,054
1887-8	122,402	177,158
1888-9	122,273	179,406
1889-90	192,332	313,572
1890-1	183,728	304,648
1891-2	187,233	281,553
1892-3	229,492	316,179
1893-4	234,231	284,964
1895-5	196,281	242,813

PLUMBERS' ASSOCIATIONS.

THE Toronto Association of Master Plumbers is doing effectual work under the direction of the enthusiastic president, Mr. W. J. Burroughes. Their meetings are now held in Pythian Hall, corner Queen and Victoria streets. Mr. Burroughes has drawn up a draft of an act providing for compulsory examination of plumbers in Ontario. This act, in its present form, is entitled "An Act to Secure the Registration of Plumbers and the Supervising of Plumbing and Drainage in the Cities of the Province of Ontario." It will be submitted for approval to the different associations throughout the province and the Secretary of the Provincial Board of Health before being presented to Parliament. As the act is claimed to be in the interest of the public, Mr. Burroughes hopes to meet with little opposition in the House.

The London Association is one of the most active branches of the Dominion Master Plumbers' Association. We are informed that the membership embraces every legitimate plumber in the city, as well as a number of others located in adjacent towns. The weekly meetings are well attended, and much interest is shown in the proceedings thereof. The president, Mr. Wm. Smith, is unceasing in his efforts to promote the success of the association.

In striking contrast with the London Association is the Hamilton branch, which has not held a meeting since July. While recognizing the benefits to be derived from an interchange of ideas as thus afforded, there is an apparent lack of energy on the part of many of the members. It is hoped that during the winter season new life will be infused into the master plumbers of Hamilton.

The plumbers and steamfitters of Great Britain have formed a national association, with a membership of 800.

ASPHALT FELTING.—In order to keep the dampness out of walls and prevent its rising from the soil, Buscher and Hoffman, of Eberswalde, apply strips of asphalt felting, as wide as the wall, in lengths of about 3 feet. The pieces overlap by a couple of inches; the pressure of the continuation of the wall, resting on this layer, secures a perfect joint. The manipulation is very simple and easier than the application of liquid asphalt, which in warm weather is not rarely squeezed out again. The insulation is not destroyed when parts of a building settle. The felting has profitably been applied in tunnels and underground structures, and has answered well in the Carlsruhe tunnel, for instance. Old buildings can also be fitted with the felting, which bears a fairly high temperature.

CORRESPONDENCE.

[Letters are invited for this department on subjects relating to the building interests. To secure insertion, all communications must be accompanied by the name and address of the author, not necessarily for publication. The publisher will not assume responsibility for the opinions of correspondents.]

HANGING INSIDE BLINDS.

Editor CANADIAN ARCHITECT AND BUILDER:

WILL you, or some of your well informed readers, kindly inform me through your columns as to the best and most economical method of arranging for and hanging two-fold inside blinds. The building in which the blinds are to be hung will be of brick, fourteen inch wall, furred and lathed and plastered on the inside. The windows are 3' 6" wide, sashes 1 3/4" thick, double hung, and there are to be heavy inside stools. The blinds are to be of black birch, and not more than 7/8 of an inch thick, and are to fold back in a box and show as panels on the side of the window when so folded; casings are molded and are six inches wide and will show square in the room. I desire to make a nice job of this work, but do not want it to cost too much. Any information through your columns will be appreciated by a

YOUNG CARPENTER IN DISTRESS.

Owen Sound, Nov. 10, 1896.

[In reply to the foregoing, we may say to a "Carpenter in Distress" that there are many ways of preparing "boxing for shutters" practised in England and in this country more or less costly, and we believe there are among our readers many expert workmen who can give intelligent descriptions of how the work may be done with efficiency and economy, and we submit the problem to them with the hope that they will relieve "A Young Carpenter" of his difficulty. THE EDITOR.]

INFORMATION REQUIRED BY BUILDERS.

SIR, I have read with pleasure the article in your journal, "Loads and Strength of Roofs." This led me to think of the advantages the builders would get if they had a card giving the weight of the different kinds of roofing material, flooring, stud partition, outside walls, etc., etc., so as to enable the builder to know at a glance the strength required for the rafters, joists, beams, etc., also the exact weight they will have to support. I have many books with those tables and formulas in them, but as they are in most cases worked with letters, I have great trouble to get at an approximate idea of the weight to be supported and the size of joints and rafters required. If you had something with examples in plain figures, then the great majority of the builders would know what to buy, and have no fears for the safety of the building that they are repairing or constructing. I enclose stamp for reply, and oblige.

Your Obedient Servant,

J. B. D.

Montreal, Nov. 5th, 1896.

[The information asked for by our correspondent is not easily obtainable, and will require considerable research and time to put in shape. We shall make an effort to supply at least a portion of it, however, through this department in the near future. THE EDITOR.

Besides indigo and purple few colors were employed by the ancients, and these were obtained for the most part from the vegetable kingdom, but their purity was so great that they have kept well to our own times, after having undergone for centuries the action of the air and the sun.

LEAD VS. IRON FOR SUPPLY AND VENT PIPES, FROM A PLUMBER'S POINT OF VIEW.*

If we consider the question as an engineer would when seeking the most suitable material for his purpose, and divest our minds of all prejudice and consideration of how it will effect our individual interest as plumbers, or the business in general, we will sooner arrive at correct conclusions. If it is truth we are seeking, and not specious argument to bolster preconceived notions, we certainly do so.

In past times lead was used by plumbers almost exclusively for water pipes and other purposes. It was the chief material a plumber was called on to use, and it was necessary for him to be most skilled in working to be a success in his business. It was almost considered the only metal fit for that purpose.

Now we find it practicable to fit up the largest buildings in the most desirable manner, with the finest open work, and not use an ounce of lead pipe. The tendency of the demand at the present time is for substitution of other metals in preference to lead in the plumbing business. This tendency is the verdict of public opinion that condemns lead, and relegates it from the position of primary importance to a secondary one in the plumbing business. We may grieve at this tendency, but it is useless for us to kick against the progress of the times. It is better that we adapt ourselves to the situation, keep in line with all improvements, and not attempt to impede them because they necessarily dispense with the skill we have acquired.

Lead pipe (which was sometimes tinned inside) was formerly considered the most suitable for the conveyance of water from the mains to all vessels used for domestic purposes. It certainly answered the purpose well. The charge of lead poisoning was sometimes laid to the use of these pipes, but few cases were ever proved. The percentage of people using this pipe suspected of suffering from lead poisoning was so small as to be of little importance.

To the Pacific coast iron pipe came with the early gold seekers, and was probably used by them as water pipe, because it required less skill to join and lay it. Black iron pipe was soon found to be useless on account of rusting, but galvanized iron pipe answered better, and was first introduced in small houses for conveying cold water only, and was not considered suitable for hot water at all. As experience showed no objectionable feature in this material, it began to be used in better houses, but for many years iron was used for cold and lead for hot water. Gradually the use of galvanized iron pipe extended for hot water, until now it is almost the only kind used. Forty years' use on this coast has demonstrated that for supply pipes galvanized pipe is well adapted. The zinc coating has proved a thorough protection which makes it very durable.

In comparing the several advantages that lead and galvanized iron pipe have when used for water supply, we find that, galvanized pipe being harder, it is less liable to be damaged by accident, as it is able to resist such accidents as nails being driven against it and the gnawing of rats.

Being stronger it requires less support and is never found hanging in festoons. It is seldom broken with fair usage, when once covered up in good condition. It seldom requires any repairs, except when it is burst with frost. It is not injuriously affected by rapid changes of the temperature of the water it carries in any degree above the freezing point, as is lead pipe if allowed room for expansion.

The cost of galvanized iron pipe and the labor needed for its use are less than for lead pipe. With the introduction of nickel-plated supply pipes for connections of open work, there disappears the last obvious advantage of lead for supply pipe. Lead pipes are often taken out of houses, to be replaced by galvanized iron pipes, but never the reverse on this coast.

If this be the result of the experiment of using galvanized iron pipe for supply pipe in a new and venturous section of the country, it only indicates what will be the result in older and more conservative sections of the country. We find plumbers in eastern cities getting alarmed at the increased use of galvanized iron for supply pipe, and claiming in the trade papers that it becomes worthless in three or four years; that it rusts at the ends and at other exposed places, and is generally no good. Forty years' extensive experience with the use of it on the Pacific Coast demonstrates that such is not the case. The continued growth of its use from a modest introduction of it as a cheap and convenient substitute to its present position, when it has driven lead supply pipe entirely out of use, and that too in face of the hostility of the men who had to work it, proves that it must have merits of no small degree.

When used as waste pipes iron pipes do not have the same advantages they have as supply pipes. Wrought iron pipe unprotected by covering is not suitable for vent pipe, and should be discarded for the reason that it rusts quickly internally, which rust soon begins to fall from the vertical portions and closes the bottom of the pipe. Galvanized iron pipe is better, but it will not withstand the action of sewage or sewer gases, and therefore is not reliable.

Iron pipe dipped in asphaltum and thus protected has no known weakness, and the great success of the adopting of iron dipped pipe for soil pipe would justify us in expecting equally good results from the general adoption of such pipe for sewer ventilation.

Lead pipe for ventilation has many advantages to recommend it if properly supported and protected. Lead pipe is capable of resisting all chemical action of sewage or gases, and, not being exposed to great changes of temperature, there is little danger of breaking by contraction and expansion, as is sometimes the case with waste pipes which convey hot water. The smoothness of the interior of lead pipe and its gentle curves make it most efficient and desirable on account of the small friction which it offers.

* A paper by William Eccles, of Portland, Oregon, in the Gas Light Journal.

REQUIREMENTS OF GOOD HOUSE PLUMBING.

A PAPER entitled "Improved Methods of House Drainage," read before the Architectural League of New York, by Mr. Paul Gerhard, C. E., Consulting Engineer for Sanitary Works, contains the following on the subject of good house plumbing:

The limits of this paper do not permit my discussing in detail the requirements of water closets, and I must pass on to review briefly the other plumbing appliances of houses.

Speaking of wash basins, we may distinguish four principal types, viz: 1, tip-up basins; 2, chain and plug basins; 3, open stand-pipe overflow basins; and 4, secret waste-valve basins.

Tip-up basins are generally condemned, because in their usual form they have objectionable features. If the receiver could only be arranged so that it would not become foul, or that it was readily accessible for cleaning, this type of basin would have many merits. It is, without doubt, very convenient in use, has no concealed overflow, no chain and plug, is rapidly emptied and flushes its waste pipe and trap well at each discharge.

The objections to the second type, the common chain and plug basin, are too well-known to need further comment. It is proper, however, to state that there has recently been put upon the market some modified forms of this type, which I consider great improvements upon the ordinary type. One is a siphon-basin, which empties rapidly and flushes its overflow at each discharge. The overflow channel is so shaped that when the plug is inserted in the bottom of the bowl and the same filled with water, the overflow is trapped. In office-buildings and in hotels, where a stand-pipe overflow basin or a bowl with waste-valve is too expensive and too complicated for general use, the siphon form of basin has much to recommend it. The other improved form is a chain-and-plug bowl in which the waste outlet has been greatly enlarged, and which has the usually hidden overflow channel made much shorter and accessible by means of a removable strainer.

The third type of basin has an open stand-pipe overflow, and there are numerous modifications of the device for raising the standpipe. From a sanitary point of view, this type has, undoubtedly, the greatest merit of all forms, still my experience has been that the general public is hardly sufficiently educated in sanitary matters to appreciate its merits. By many this form of basin is utterly condemned on account of its odd shape and appearance. The favorite form of basin is just the one which has the most objections from the hygienic standpoint, namely, the bowl with secret waste valve. To discuss its objectionable features in detail would lead us too far.

Regarding that valuable fixture for personal cleanliness, the tub or bath-tub with its various modified forms, such as the foot-tub, the sitz-bath, the hip-bath, the bidet, etc., I would state that tubs of wood lined with copper are less used than formerly in private houses, probably because they always require some sort of wooden casing, and also because they lose their bright appearance in use. Enamelled iron tubes, standing free from the wall and raised from the floor, constitute a satisfactory sanitary fixture, which is only surpassed by the beautiful all porcelain bath-tubs. Both kinds of tubs are now obtainable with a glazed roll rim, thus doing away entirely with all woodwork. I ought, perhaps, to mention in this connection, that a great improvement in the manufacture of American earthenware has recently taken place, and that it is now for the first time possible to obtain porcelain bath tubs made in this country. In regard to the appliances used for holding water in the bath tub, and for emptying the same, much of what I said of wash basins applies here. In this matter I may appear to you old fashioned, when I state that my decided preference is for an open stand-pipe overflow.

For baths in public institutions, for baths in factories, and for people's baths, there is a growing tendency to discard the tub bath in favor of the rain or spray bath, which is greatly superior from a sanitary point of view, besides having many economical advantages.

Slop sinks and housemaids' sinks are obtainable in a variety of serviceable forms, most of them excellent from the sanitarian's point of view. I would only remark that a flushing cistern is quite as essential in the case of a slop sink as in that of water closets. An ingenious and novel arrangement consists in a slop sink, which flushes itself automatically each time slops are emptied into it.

Kitchen sinks are likewise obtainable in a variety of materials. This fixture is much improved by changing the dribbling stream passing through its waste into a quick and effective flush. Attempts in this direction have been made with some success, and the devices employed are certainly worth considering. Incidentally, the question of avoiding the kitchen grease nuisance is thereby solved, in a better way, to my mind, than by the employment of grease traps at the sinks, which invariably constitute a nuisance, are usually forgotten or neglected and are not to be recommended. I must content myself with a mere allusion to the subject.

Of urinals, it is only necessary to mention that in private houses their use is not to be encouraged, as the fixture is very difficult to keep clean. In offices and in public buildings, such as hotels, railroad stations, court houses, etc., the fixture is a necessity, and great attention is required not only in the fitting up, but in its maintenance. The projecting lip of porcelain urinals seems to me to be of doubtful advantage. One point in the fitting up of the fixture is worthy of mention: The bowls are generally set up too high from the floor slab. I find it is better to set them at a height not exceeding twenty-two inches from top of lip to floor line, instead of twenty-four to twenty-six inches, as is customary. The floor-slab is thereby kept more readily free from drippings.

In fitting up plumbing fixtures, the chief aim should always be the avoidance of woodwork at and around them. All fixtures should stand free from the walls and be accessible on all sides. Even the seats of water-closets are now attached directly to the bowl, the closet thus stands absolutely free and detached from the wall, and the entire fixture can be reached for cleaning and for repairs. In one respect, however, modern plumbing fixtures are open to considerable improvement: I refer to the undesirable noisiness accompanying the flush and the discharge of the fixtures. This problem, as experience teaches, is not easily solved.

The time at my disposal permits only a brief allusion to the testing of plumbing work. All work should be tested before acceptance, as knowledge of the safety of the plumbing work can only be obtained in this way. I regret to say that I have found only very few mechanics doing plumbing who apply to their work any test, except where this is specially insisted upon by the architect or engineer. To my mind, it is one of the most important duties which architects owe to their clients, to see to it that all work is tested. For new work we have the water test and the air pressure test. This should include not merely the main horizontal lines and the vertical stacks, but likewise all the branches, and the brass ferrule joints. The finished work should be tested by the peppermint or by the smoke test, which help to show imperfections in the joints of nickel-plated piping and at the floor joints. In the inspection of old

work, the water test, which is the best test, cannot, for obvious reasons, be applied, and here the smoke test, or the test with oil of peppermint, intelligently applied, give indications as to the condition of the work.

A great step forward would be made and plumbing work vastly simplified, by abolishing, or at least modifying the trap vent system.

There are at present two quite different methods of arranging the system of trapping the fixtures in a building. In the one system, which is in accordance with the majority of plumbing regulations, and is the one at present enforced in New York City, all traps must be back aired or vented. We thus obtain a duplicate system of pipe lines, the work is complicated, more expensive and may become more unsafe, on account of the greater number of pipe joints and the possibility of "by passes." The other system the one pipe system, as we may call it is distinguished by its greater simplicity, economy and, as I maintain, by its greater safety. This method substitutes non-siphoning traps or anti-siphon trap attachments for the cumbersome method of back airing. In this system, all main soil and waste lines must be quite as fully ventilated by extending them the full size up to the roof as in the usual method. All fixtures are located directly at the lines carried up to the roof, or within a very few feet of the same. Siphonage of the traps is impossible under the ordinary conditions, quite as much so as in the back airing system. You will find the majority of plumbers opposed to the new system: for while it simplifies the work, it reduces the amount of piping used and thereby the cost of the work. There is also much prejudice against the proposition, many plumbers seeming to fear that by putting themselves openly on record as in favor of it, they would by others be considered as not quite up to date in plumbing matters. The fact remains undisputed and I have demonstrated it in many cases in my practice that the new method is, at least, quite as safe as the old one. I venture to predict that in a very few years plumbing laws will be so modified as to leave it optional with the owner or architect of a building which method he will adopt.

This leads me to say a few words in regard to plumbing rules and regulations, in particular of those in force in New York City. Further advancement in plumbing requires the revision and improvement of the plumbing by-laws of the building department. Far be it from me to underrate the good which the present rules have accomplished in the past. Ours is not, however, an age in which we can at any time afford to stand still. Constant progress is made in every department of construction and the researches of the practical sciences are everywhere utilized and embodied in actual practice. Let us hope to see soon a revision of our plumbing laws. Be it largely copied by other cities. We cannot afford to fall behind in this matter. Our present rules are too indefinite in many details; they are much too arbitrary in others. Take, for instance, the question of sizes of drain pipes, of soil pipes, of vent pipes, the diameter of traps, etc. There is certainly now sufficient practical experience available to lay down more definite rules as to sizes. The rules should also in the future prohibit fixtures which sanitary science has long ago recognized as being absolutely bad. Pan closets, wooden sinks and wooden wash tubs should be discarded, and privy sinks should no longer be tolerated.

MANUFACTURES AND MATERIALS

BRICKS FOR WELL LININGS.

Of patent bricks there are no end, but we know of none that fully satisfy all the requirements of the well-sinker, says the British Clay Worker. Our readers will probably say that our view, in that case, must be very limited—they could tell us of plenty of bricks that answer the purpose very well indeed. But we shall convince them to the contrary, and we throw out this suggestion with every confidence. Patent cement blocks have been much employed in recent years for well lining; they are made on the interlocking system. But whether it be cement blocks or bricks, the effective locking too often takes place horizontally only. It seems to be forgotten that there is considerable pressure from behind, and bulging inwards too often results. That is a fault, however, that can easily be remedied, and we are not so much concerned with that at the moment as with the manufacture of a type of brick that will permit the well sinker to gradually decrease the diameter of the well with the usual ledges and steps. With a deep well it is customary to sink to a considerable depth of a certain diameter, say 6 feet to commence with; then the diameter is decreased to say 4 feet 6 inches. It is at the point of alteration of the diameter (which alteration may be allowed three or four times in a very deep well) that the weakness results, and it is there that we would advise the use of a different type of brick to any at present employed, to our knowledge. The change from 6 feet to 4 feet 6 inches ought not to be sudden, but gradual; interlocking bricks should always be used except where the strata bored into are of a very dry character, and no difficulties result from pressure of superincumbent weights. And these bricks should be made by proportionately decreasing from the one diameter to the other. The bevelling off at present creates a spot for the lodgement of any sediment, any weeping and leakage too frequently takes place at such points. This would no longer be the case were suitable non-porous bricks of an interlocking decreasing diameter type employed at such junctures.

Some beautiful specimens of stone have recently been taken out from the vicinity of Lake Manitoba.

Mr. G. C. Morrison, of Hamilton, has invented a seamless tube hot water boiler for domestic heating purposes.

It is reported that a company has been formed in Toronto to manufacture bricks on an extensive scale at Rossland, B. C.

The Richmond Times states that the asbestos mines near Danville, Que., have been sold to a joint stock company for $2,500,000, the deal having been completed in England between Mr. Boas and an English syndicate.

Mr. C. Sontum, commercial agent for Canada at Christiania, Norway, has just sent to the Department of Trade and Commerce a letter in which he speaks of a successful shipment of steam radiators from Toronto. He emphasizes the importance of manufacturers branding their goods with the name "Canadian," or "Manufactured in Canada."

The slate industry of New Rockland, Que., is being pushed with the usual vigor, a valuable new bench of slates being reported from the eastern side of the quarry, so that the work will be extended at the surface instead of sinking to a greater depth. The slate quarry and works at Danville, Que., are at present closed pending the disposal of a large quantity of merchantable material on hand.

A new material has been discovered for insulating pipes, which is made of silex, which, when ground into fine particles, is to be used to surround the conductor wire with, inside an iron pipe, which should be packed down. It is claimed that the silex will not burn, or melt, or rot, or leak; it is said to absolutely prevent electricity coming into contact with any other substance inside a building where it is used.

According to the annual report of the Ontario Bureau of Mines, the production of Portland cement in Ontario in 1895 was 58,699 barrels, as against 30,580 barrels in 1894. The value was $114,332, as against $61,660, and the wages paid were $46,000, as against $31,858. It is noticeable, however, that this is but a small proportion of the total used, the entries of Portland cement for home consumption for the fiscal year 1894-95, exclusive of that imported for Dominion government use, being 196,281 barrels, valued at $242,813.

CANADIAN ARCHITECT AND BUILDER.

VOL. IX.—No. 12. DECEMBER, 1896 PRICE 20 CENTS $2.00 PER YEAR.

—THE—
CANADIAN ARCHITECT AND BUILDER,
A Monthly Journal of Modern Constructive Methods.
(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD).
PUBLISHED ON THE THIRD THURSDAY IN EACH MONTH IN THE INTEREST OF
ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.
C. H. MORTIMER, Publisher,
Confederation Life Building, - TORONTO, CANADA.
Telephone 2362.
Branch Office: NEW YORK LIFE INSURANCE BUILDING, MONTREAL.
Bell Telephone 2299.

SUBSCRIPTIONS.
The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.
Prices for advertisements sent promptly on application. Orders for advertisemnets should reach the office of publication not later than the 12th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.
Contributions of value to the persons in whose interest this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publisher of any irregularity in delivery of paper.

ONTARIO ASSOCIATION OF ARCHITECTS.

OFFICERS FOR 1896.

PRESIDENT	H. B. GORDON, Toronto.
1ST VICE-PRESIDENT	J. GEMMELL, Toronto.
2ND VICE-PRESIDENT	JOS. W. POWER, Kingston.
TREASURER	EDMUND BURKE, Toronto.

COUNCIL:

F. J. ALEXANDER	Ottawa.
THOS. FULLER	Ottawa.
E. J. LENNOX	Toronto.
J. M. MOORE	London
W. R. STRICKLAND	Toronto

REGISTRAR AND LIBRARIAN:
W. A. LANGTON — Canada Life Building, Toronto.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.

OFFICERS FOR 1896.

PRESIDENT	A. F. TAYLOR, F.R.I.B.A., Montreal.
1ST VICE-PRESIDENT	J. F. PEACHY, Quebec.
2ND VICE-PRESIDENT	A. RAZA, Montreal.
SECRETARY	J. VENNE, Montreal.
TREASURER	E. MAXWELL, Montreal.

COUNCIL:

A. C. HUTCHISON	Montreal.
JAS. NELSON	Montreal.
J. WRIGHT	Montreal.
ROBT. FINDLAY	Montreal.
CHAS. BAILLAIRGE	Quebec.
F. H. BERLINGUET	Quebec.

AUDITORS—G. E. TANGUAY and H. C. NELSON, Montreal.

TORONTO BUILDERS' EXCHANGE.

BOARD OF DIRECTORS:

JOHN ALDRIDGE, President.
THOS. CANNON, Jr., 1st Vice-Pres.
JOHN VICK, 2nd Vice-President.
DAVID WILLIAMS, Treasurer.
WM. BOOTH.
JOHN WICKETT.
JOHN RUSSELL.
H. LUCAS.
JOHN YOKES.

JOHN L. PHILLIPS, Secretary.

TO ADVERTISERS.

For the benefit of Advertisers, a copy of this journal is mailed each week to persons mentioned in the CONTRACT RECORD reports as intending to build, with a request to consult our advertisement pages and write advertisers for material, machinery, etc.

Tall Building.

THE completion of a ten-storey building in Toronto, and the proposal to erect a fourteen-storey structure on the site of the present St. Lawrence Hall Hôtel in Montreal, would seem to be evidence that the craze for tall buildings which has marked Chicago and New York for several years past, is exerting its influence upon the architecture of our Canadian cities. It may not be out of place at this juncture to point out that in the American cities we have named popular favor is being withdrawn from these abnormal specimens of nineteenth century architecture, and legislation has been introduced for the purpose of restricting the height to which buildings may be erected in the future. Another potent influence tending to discourage this style of architecture is that the number of such structures already built so far exceeds the demand that the owners are said to have been compelled to reduce rentals by 50 per cent., while some of the high structures in Chicago which were designed for office purposes are being used as storehouses, in which capacity it will of course be impossible to obtain a fair return on the owners' investment. The unsatisfactory experience of our American neighbors in this direction, coupled with the lower land values in Canadian cities, would seem to render inadvisable the erection of structures exceeding say six or eight storeys in height.

The Safety of Elevators.

IN New York recently four persons had their legs broken by the dropping of an elevator. This elevator is said to have been of the most modern type, fitted with so-called safety catches, which in the event of the breaking of a cable or other accident, are supposed to grip the slides and hold the elevator in place. The accident referred to points to the necessity for protective devices which can be depended on to accomplish their purpose. There is also a greater degree of competency required on the part of persons in charge of elevators. Not only should the employment of lads for this purpose be forbidden, but the man who is placed in charge of an elevator should be required to become thoroughly posted regarding the method of its construction and operation. To illustrate the present condition of knowledge, the writer recently made a few inquiries from a young man in charge of an elevator in a modern office building as to whether there was anything to prevent the elevator from falling in case of accident to the guys. He was assured that there were catches for this pur-

v.8-9
Canadian
archi
and

pose. On being asked to point out the whereabouts of these protective devices, and the method of their application, the attendant was unable to do so. All he knew about the matter was that he had been told the elevator could not fall, and he had gone on operating it in the calm assurance that no accident could happen, and without making any effort to investigate for himself the actual conditions.

Duty on Artists' Materials.

The request recently presented to the Government Tariff Commissioners by representatives of the Art Societies for the removal of the duties on artists' materials, is one with which the government should comply. The imposition of these duties for many years past, has not, so far as we know, resulted in any attempt being made to manufacture these materials in Canada. Presumably the market is too limited to warrant such an attempt. Under these circumstances the duties constitute a burden upon the art workers of the country, and tend to retard the development of art in the Dominion. It would therefore seem to be proper to remove them in part or altogether.

Care in Designing.

Too much care cannot be exercised by the architect with the details of his design. A seemingly trifling error of judgment in designing one particular feature often results in marring the general effect of the building. Instances have come under our notice in which for lack of a particular curve the outline of a verandah, otherwise satisfactory, proved defective in the eyes of the architect by whom it was designed, who felt a constant desire to pull the work to pieces and reconstruct it. Such a slip is doubly annoying to the architect if, having been dissatisfied with the effect of the detail on paper, he has allowed it to be put in concrete form, in the belief that in situ it would present an improved appearance. This rarely happens. Therefore the architect who is unfavorably impressed with the appearance on paper of any feature of his design is likely to save himself lasting disappointment by giving the problem further study, and making such changes as in his judgment will secure a satisfactory effect.

The Buffalo Breakwater.

Much interest was taken by both Canadian and United States stone dealers in the awarding of the contract for the new breakwater at Buffalo, for which the government made an appropriation of $2,000,000. Twelve tenders were submitted, several of which were based on furnishing Canadian stone from quarries in the township of Bertie, across the lake from the harbor and only four miles distant. Provisional clauses were inserted that the stone was to be shipped from Canada in the name of the United States, a proceeding which permitted of the importation of the stone without duty. As there appeared to be a fighting chance for the adoption of Canadian stone, steps were at once taken to head off such a movement, and the introduction of a bill in the House of Assembly at Albany providing that only citizens of the United States be employed on Government work was threatened. Upon opening the tenders for the breakwater, however, the figures for the supply of both Canadian and American stone were nearly the same, and it was resolved to exclude the Canadian product.

Building Conditions.

Much satisfaction is being expressed by architects, builders, and all persons in any way connected with the building interests, with the extremely mild and fair weather which has prevailed to within a few days of the close of the year. In consequence of this unusual condition, a large amount of work in the way of completing buildings, and carrying out repairs and improvements, has been in progress, which otherwise must have been postponed until spring. Unless we should be unfortunate in having a late spring, the gap between the building season of 1896 and 1897 will be much shorter than usual, a circumstance which would be appreciated by all whose interests are dependent upon activity in the building industry.

The Ontario Architects' Bill.

It is a pity that some of the people who were referred to by a correspondent in our last issue as objecting to the attachment of a legal status to the title "architect" do not express their views in print or write enquiring if they are right in their suppositions of what the proposed Architects' Bill will enact. There can be no doubt that there has been much misconception of the nature of the bill and much unnecessary anxiety, on the part of builders especially, as to how their interests will be affected if the bill passes. It is not easy to see upon what this anxiety is based; but, if stated, we are confident it will be found to be as baseless as Mr. Ireland's conception of the Association bent on keeping out new comers by examinations turns out to be, in the light of the Registrar's letter in another column saying that the Association does not wish to control the examinations. It is essential in introducing such a bill to safeguard all existing interests from sudden change, and it is not likely that, if the bill passes, anybody will be able to perceive any immediate effect. Ultimately, no doubt, the profession of architecture will, as the promoters of the bill expect, be established upon a higher plane; but why any other branch of the building trade should suffer in consequence, it is hard to see. For builders in cities, who for the most part erect architects' buildings, an improvement in the architects' art will not mean either less work or less good work; and improvement in the architects' skill will be a direct gain, for it cannot be denied that the builders' gains are sometimes seriously impaired by unscientific methods on the part of the architect and the need of making good his deficiencies. The country builder perhaps regards himself as somewhat in competition with the architect. However that may be, it is clear that the architect can never be in competition with the builder. The builder must still build everything that is built, and plan a great deal of it too. The proposed bill is not a law to make people employ architects, as some people seem to have thought, but to make architects better worth employing. It is intended to raise the quality of the architect and the character of his profession; not to insist upon every little piece of work being put into his hands. It would doubtless be an ideal state of affairs if every village store and cottage was the work of a first-rate designer, but work of this kind will always be done by builders. We do not think, however, that the design of such buildings will be unaffected by improved design on the part of architects, for the builder is quick to pick up new ideas, and the better the work of architects the better his work will be.

BY THE WAY.

A Norwegian firm is reported to be engaged in the manufacture of bricks from condensed petroleum for fuel purposes. These bricks are said to give out four times as much heat as coal, and without smoke. In view of the attention which the production of petroleum is at present receiving as the result of recent discoveries in Western Ontario, this might be an opportune time to experiment with the manufacture of petroleum fuel bricks in this country.

× × × ×

A contractor from Uncle Sam's domains came to Toronto not long since for the purpose of tendering on a contract about to be let. After taking the quantities from the specifications and making his estimates thereon, he enquired in a matter-of-fact manner what commission he should allow for the architect. He seemed greatly surprised on being informed by the architect that in Canada it is not customary for architects to accept commissions from contractors. The inference might reasonably be drawn from this incident that the practice of accepting commissions from both client and contractor is one which obtains to some extent across the border.

× × × ×

As an illustration of the old saying that one must look abroad for home news, I find the following paragraph in an English technical journal:- "It is said that many hundred rolls of wall paper with solid black grounds, designs for the most part in slate-colour, are yearly used in Canada by French Canadians. These people, when they go into mourning, never do things by halves, but even hang their private apartments with these gloomy papers, indicative of a death in the family." The improbability of this story was so evident that I caused enquiries to be made in Quebec regarding it, and found as I expected, that there was not the slightest truth in it. In fact, the very reverse is true—the French Canadians being partial to lively colors.

× × × ×

Dropping into the office of a well-known solicitor in Toronto the other day, I was informed of a peculiar incident which occurred in connection with the testing of cement. Two buildings were in course of construction, by different contractors; the same architect and clerk of works having charge of both. The contractor for one of the buildings obtained a quantity of cement which he believed was according to specification and would stand the necessary test, but it was refused by the architect and his superintendent as being of an inferior grade. It was consequently stored in a downtown warehouse. The two contractors, being on friendly terms, the one whose cement had been refused sold the same cement to the contractor of the other building, and it was accepted without a word of complaint. What rendered the transaction still more peculiar was the fact that the specifications governing the cement were exactly the same in both cases. Either the architect and his clerk were unduly severe on the first contractor, or allowed inferior materials to enter into the construction of the building in which the cement was used.

It is reported that the Danville, Que., Slate and Asbestos Co. is to be capitalized at $2,000,000. English capitalists lately visited the works in connection with the proposition.

DUTY ON BUILDING MATERIAL.

Messrs. Joseph Wright, president, J. W. Taylor, manager, and David Carlisle, director, of the Toronto Radiator Manufacturing Company interviewed the Tariff Commissioners at Toronto and asked that the duty on radiators be allowed to remain as at present, the duty of 27½ per cent. being considered sufficient under certain conditions. They were, however, desirous of having a bonus of $4.80 per ton on exported radiators, whether made of Canadian or American iron. The competition from the United States gave considerable cause for complaint. Labor was cheaper there than here, was of an inferior class, and the vast expanse of this country made freight expensive. Mr. Taylor said that radiators sold in Toronto 30 per cent. cheaper than in the United States, and the cheap rate of freight, viz.: 14c. from Boston to St. John, compared with the 58c. rate from Toronto to St. John compelled the Canadian concern to sell 10 per cent. cheaper in St. John than the United States firms did, in order to meet the American competition. The present duty of 27½ per cent. ad valorem was, if anything, not high enough, as it gave the American concerns an opportunity to work off their surplus stock in this country.

At Hamilton representatives of sewer pipe companies asked for the imposition of a duty of $5 per ton on sewer pipe. The present duty averages 35 per cent. In the event of there being no specific duty they asked that the value for duty be placed at 70 per cent. off the American list instead of 77 per cent.

Among the reasons presented for a specific duty was that double-strength pipe was frequently admitted as ordinary standard pipe, whereas it should be 20 per cent. dearer. There were in Canada five factories, but there was no association for keeping up prices.

William Findlay, builder and roofer, asked for a lowering of the duty on slate for roofing purposes. He said the duty used to be 80 cents per square, but it was subsequently changed to 20 per cent. ad valorem, and at the last revision was fixed at 30 per cent. He asked that the duty again be reduced to 20 per cent. The source of supply was chiefly in the United States. There was one quarry in Quebec, but that concern could find a market in its own district for its output. The difficulty in obtaining supplies was often great, and builders were seriously hampered in their work. With a lower duty, slate would be cheaper and would be more generally used.

The Hamilton Blast Furnace Company asked for protection for their works. The capacity of the furnace was stated to be two hundred tons of iron per day, but the average turnout was one hundred and twenty tons. They intended next season to bring the ore from Lake Superior by water transportation. Since starting they had purchased Canadian ore, found chiefly in Hastings county, 10,000 tons, costing $35,000. They have produced 21,000 tons of pig-iron. Of this 10,000 tons have been sold and delivered, and 4,000 tons are booked, leaving a little over 6,000 tons not sold. They have paid in inward freight on ore $60,000, and $7,000 in outward freight. Their wage bill amounts to $1,150 a week, making a total paid in wages $46,000. If the present protection were withdrawn they would lose the whole of their investment. If the Hamilton furnace was well encouraged it was the intention to go into the manufacture of steel, employing at least 500 men. It was stated that about 16,000 tons of pig-iron were produced in Canada in a year from five blast furnaces.

v.8-9
Canadian
arc

PROPOSED AMENDMENT OF THE O. A. A. ACT.

The Ontario Association of Architects have wisely decided to renew their efforts for the amendment of the Ontario Architects' Bill, in a manner to in future restrict the use of the word "architect" to properly qualified persons. The relation which the work of the architect bears to the health of the community and the extent to which the safety of human life and the interests of property are dependent upon his knowledge and skill, demand that the public should have means of knowing who are qualified to call themselves "architects." It should be clearly understood that no attempt is being made to compel persons who desire to erect buildings to employ a qualified architect to prepare the plans and supervise the construction. If they have sufficient confidence in the ability of some person who is not entitled to call himself an "architect," to prepare plans and carry out the work, they are at liberty to entrust to him the undertaking. In view of this freedom on the part of anybody to prepare plans for buildings so long as he does not designate himself as an "architect," and of the public to employ a properly qualified architect or not, as they may choose, we fail to see any reasonable ground of objection to the desired legislation.

A REQUIRED DISTINCTION.

Even great men do not hesitate on occasion to express an off-hand opinion on subjects of which they possess but a surface knowledge. Greater care should be exercised by such persons in this regard, for the position they occupy in the community by reason of their superior attainments in a particular field of learning or effort, is apt to lead the public to attach great importance to their opinion on all subjects. It does not follow because a man is a clever lawyer that, therefore, he is competent to express an opinion upon architecture, or that he is familiar with the conditions under which a large proportion of the buildings erected are designed and constructed. It was undoubtedly ignorance on this point that induced a prominent lawyer of Toronto to make an indiscriminate onslaught, before an audience he was recently addressing, upon architects for their alleged inability to put up beautiful buildings. This talented lawyer evidently was not aware of the fact that perhaps most of the buildings in the locality to which his remarks bore reference were constructed entirely without the agency of a properly qualified architect the the speculative builder having alone been responsible for their design and execution.

There is here a strong argument in favor of the effort which the Ontario Association of architects is making to induce the legislature to restrict for the future the use of the title "architect" to persons who are properly qualified for the practice of the profession. So long as everybody who may undertake to put up a building can call himself an architect, the public is unable to distinguish who are properly qualified men, and naturally enough, under these circumstances, the men of taste and skill are brought under public condemnation on account of the lack of taste displayed by those who possess no qualifications for the work which they undertake to do.

W. B. Mundy, architect, formerly of Hamilton, Ont., is erecting the new Chicago Fair building, which is to cost one million dollars.

COMBINATION HEATING.

The question of furnace and the best form of coil or heater adapted to it being decided, says Mr. J. W. Hughes in an article on this subject in the Metal Worker, the fitter has next to plan or lay out the mains and branches to suit different coils and radiators. As the buildings to be warmed differ in plan, so will the placing of pipes vary, and as long as the general principles controlling the circulation of water are not violated the apparatus will work. But there is no doubt but that certain plans on a given job will work better than others. The main object is to arrange the pipes to allow the greatest freedom of circulation. Undue friction must be avoided by not having the pipes too small, and by having too many sharp turns, and above all, the pipes must be arranged to allow of their being filled "solid"—that is, that there be no air pockets. As the water in the heater becomes hot it expands and becomes lighter, and by the law of gravitation ascends to the rising main or flow pipe, the colder water flowing in by the return. As long as the heat is applied this goes on continuously; but as the difference in the weight of the two columns of water viz., that in the flow and return is very little, it takes very little to stop it. A bubble of air in the pipes will stop circulation by separating the water.

The lesson to be learned is to avoid everything that will prevent the pipes and coils from being solidly filled with water, and that will prevent the water from flowing freely in the direction which it should go that is, up from the heater when warmed, and back and down to it when heat has been imparted to the air of the apartment.

The combination system is of necessity restricted in a greater or less degree by the size and make of the hot-air furnace, and the possibility of fitting a given sized coil or heater in it. The fact must not be lost sight of that in a building warmed with a combination apparatus, air from the furnace is the principal factor, the heat from the hot water circulation combined with it being a useful adjunct or assistant for warming certain portions of the building to which the hot air cannot gain access, or to increase the heat where the hot air would only be partially sufficient. Valves on coils should be avoided. To shut off a coil on a general circulation makes a serious disturbance that is apt to cause the formation of steam, with the accompanying noise, and when the checking of the fire causes the condensation of the steam the pipes will no longer be solidly filled with water, and there will be a poor circulation or none at all.

The following proportions of heaters or coils in furnaces to the amount of heating coils or circulation in rooms are from actual jobs that worked well: 30 ft. of 1¼ in. spiral coil in dome of furnace with 1¼ in. flow and return, and 1 in. and ¾ in. branches heated 1,300 ft. of 1 in. circulation coils; 11 ft. 1¼ in. heater pipe did the same for 380 ft. of ¾ in. coils; 11 ft. 1¼ in. coils with 1¼ in. flow and return and 1 in. branches took care of 260 ft. of 1 in. circulation coils; 9 ft. 6 in. of 1½ in. heater coil with 1¼ in. flow and return mains and 1. in branches to coils, carried 240 ft. of 1 in. circulation; 13 ft. 7 in. of 1 in. coil with 1 in. flow and return branches off to 1 in. and ¾ in. supplied 550 ft. of 1 in. coils; 12 ft. 7 in. of same sizes to 325 ft. was a success again; 12 ft. of 1 in. to 320 ft. of coils worked well; 11 ft. 10 in. of 1 in. with same sizes for distribution carried 439 ft. of coils; 14 ft. 6 in. of 1 in. to 400 ft. same sizes, and 13 ft. 2 in. of 1¼ in. with 1¼ in. flow and return 1 in. and ¾ in. distributing branches, to 490 ft. of 1 in. coils gave good results.

ARTIFICIAL MARBLE.

A company is said to have been recently formed in Toronto with the purpose of manufacturing artificial marble from gypsum, by a process invented by Mr. Geo. W. Parker.

The material is made into clocks, pedestals, table tops and other fancy articles for which marble is frequently employed. The gypsum, while in its crude soft state, is cut into the desired form, being afterwards subjected to a chemical solution and polished. Prof. Coleman, the well-known geologist of the School of Practical Science, Toronto, speaks of the new material as follows:

"I have examined with great interest the specimens of 'artificial marble' shown me, and have discussed the patented process by which they were made. Mr. Parker, of Michigan, the inventor of the process, explained his method viz: Dehydration of gypsum by heat, continued for a few hours, soaking the dehydrated gypsum with sulphate of alumina solution and then drying the mass operated upon. By this means the gypsum, which is soft and easily cut with a knife, or turned on a lathe, is transformed into a hard substance very much like marble and capable of the same uses. The raw material is very cheap and obtainable in large quantities; the treatment is simple and the result surprisingly good. A specimen of gypsum from western Ontario was given to Mr. Parker for treatment after being initialled by myself, and a fragment broken off for future identification of the mass. After treatment in the way mentioned, I found that it filled the fragment broken off and was evidently the identical mass of gypsum from my collection at the School of Science. But its properties were quite changed; it is even harder than marble, which it closely resembles, and is not attacked so readily by acids, which is a point in its favor. So far as I have examined into the process, I am very favorably impressed by it. A cheap and easily worked substance is changed by two or three days treatment of a simple and inexpensive nature into a substance as beautiful and apparently as durable as marble, which is very costly when of good quality."

CHIPS.

The new management of the St. John's Stone Chinaware Company, of St. John's, Que., have given notice of application to the legislature for a special act of incorporation.

The Canadian Society of Civil Engineers, at their regular meeting on the 17th inst., will discuss what action should be taken in view of the expiration on the 1st of May next, of the lease of the rooms at present occupied by the Society.

The eleventh annual meeting of the Canadian Society of Civil Engineers is announced to take place at the society's rooms, 112 Mansfield street, Montreal, on Tuesday, January 12th. The council for 1897 will be elected and other important business transacted.

A new heating and ventilating apparatus has lately been placed in the Pictou Academy building at Pictou, N. S. The building is heated by two separate systems of heating, direct and indirect. The first named consists of radiators in the halls and coils in the rooms, the coils to be used only in the coldest weather. The indirect system is supplied by fresh air from the outside, which enters in the basement and is warmed to the required temperature, being then admitted to the rooms through large registers. Mr. Frank Powers, of Lunenburg, was the contractor for the heating work, and Messrs. Elliott & Hopson, of Halifax, were the architects.

TESTS OF CONCRETE.

Some important tests of concrete were recently made at McGill University, Montreal, by Messrs. Theo. Denis, G. G. Hare and Carl Reinhardt, the results of which will be found below. The experiments are rendered particularly interesting by the fact that the general opinion of the effect of water on cement is somewhat erroneous. Following is the report of the tests as presented at a meeting of the Canadian Society of Civil Engineers:

Of late monolithic works of great importance have been carried out, and every day concrete, as building material, is creeping to a foremost place.

Although cement testing proper has been subjected to elaborate, scientific and practical investigations, very few researches, and especially normally conducted researches, have been made on the strength and behavior of concretes and betons. This probably is due to the fact that for such experiments heavy and costly apparatus is needed. Investigations on small specimens would be useless, and conditions approaching as nearly as possible to practice have to be followed.

The following are the results obtained from a series of experiments made by students of McGill University, 1895-96.

The object of this first series of experiments is to determine the effect of different per cents of water on the strength of the concrete. The limits were 16 and 30 per cent. of water, by weight of cement and sand, which are beyond the extremes of practice on both sides.

CEMENT.

The cement used was, of course, the same brand throughout the series. It was a German Portland of good quality, slow setting, on which separate sand tests were made in connection with this series. The results are tabulated below.

SAND.

This was clean, coarse, angular, dry sand of good quality, of slightly higher grade than usual practice.

STONE.

This was broken limestone of such size that the pieces would have passed through a ring 1¼ inches diameter. They were unscreened and just as they came out of the breaker. Consequently a slight amount of dust was mixed with them. They had to be broken a little smaller than in actual practice. The blocks of concrete being only one cubic foot, it was thought that more accurate results would be obtained in this way.

MOULDS.

The moulds were made of ¾ inch plank, lined with sheet zinc. They were 5 feet long, 1 foot high and 1 foot wide, divided into four compartments, which would mould four cubes at once, of dimensions 1 x 1 x 1 feet, forming specimens large enough to investigate seriously upon. These were removed by unscrewing one side of the box and sliding them out. Care had to be taken to oil the sides of the moulds slightly before ramming the mixture in them, to avoid trouble in getting them out.

CONDITIONS OF MIXTURE AND PROPORTIONS.

The proportions adopted for this series were one of cement, two of sand, and four of stones, by weight, the proportion of water being based on the weight of sand and cement.

The cement and the sand were first thoroughly mixed dry, then the water added gradually. The stones were

then thrown on this mortar, spread out, and the whole vigorously and very thoroughly mixed. The fresh concrete was then placed into the moulds and rammed in 1½ to 2 inch layers.

RAMMING.

The rammer was a block of hard wood 2 feet long by 2 x 2 inches, with a lathe turned handle. It was not very easy with this to ram uniformly, even throughout one block, and this is one of the main sources of discrepancies in this series of experiments.

It was thought that a reduction of the breaking loads to a standard weight of the blocks would be only fair, and would slightly improve the results.

GROUPING OF TESTS.

The tests were made at one week, four weeks, and two months, and the results grouped accordingly, that is to say, the one week tests, with different per cent. of water, compare between themselves, four weeks and two months likewise. Parallels between the results, at different ages, cannot be drawn on account of some specimens having been prepared under widely different conditions. For instance, the results at two months are exceedingly low as compared with those obtained at one and four weeks. This is due to the fact that these two months specimens were the first prepared of all, and this before the cemented trough in which they were to be immersed was completed. Consequently, they were kept 8 to 10 days longer than the others in the dry air of the laboratory, which seems to have had a disastrous effect on them. But in spite of these slight drawbacks, the annexed table shows that up to 24 per cent., the percentage of water has not a very great effect on the strength. This is an important point, for below 20 per cent. the mortar obtained is rather dry and very difficult to handle.

But beyond this limit of 24 per cent. a greater proportion of water seems to weaken the concrete considerably.

This limit is very sharply defined in the adjoining table, where an additional 2 per cent of water from 24 to 26 per cent. weakens the concrete by almost one-half for the one-week tests. It is, however, interesting to notice that strength is almost completely recovered with time, the four weeks test showing the weakening limit to be between 26 and 28 per cent., and the two months between 28 and 30 per cent. So that if immediate strength be not required of the concrete structure, 28 per cent. of water will not affect the ultimate resistance it allowed to stand two months.

In the parallel sand and cement tests the weak line is not so sharply defined, but yet it is sufficiently so to show that the same statement applies. The tests in this case show a marked weakening between 14 and 16 per cent. of water for the one week, which strength is ultimately recovered, as is shown by the four weeks and two months test.

The low limit of 14 per cent., as compared with 24 for the concrete, is probably due to the fact that the stones of the concrete, on account of their porosity, absorb a part of the water.

The table shows that the great density is obtained with 16 and 18 per cent. The weights of the cubes beyond this decrease up to 24 and 26 per cent., where they are again nearly equal in density to the 16 and 18 per cent. of water. Therefore this 24 and 26 per cent. seems to be the point where the best practical results are obtained, because 16 and 18 per cent. make up too dry a concrete to allow of easy handling.

Another point incidentally comes up. Attention has been drawn to the poor results obtained by the same tests and reason of long exposure to dry air given. This shows up a very important point, namely, the necessity of covering up carefully all concrete and cement works exposed for any length of time to dry air and sun. The bad effect of these agents is plainly demonstrated, and it is doubtful whether much strength would ultimately have been recovered.

It is also interesting to notice the results obtained by the concretes made of 1 part of cement, 2 of sand and 5 of stones, and 1 cement, 2 sand and 6 of stones. The specimens of these compositions gave results equal to concretes 1, 2, 4, showing that for strength they are as good as the ones containing a less proportion of stones, while being much more economical.

These experiments are as yet very incomplete. But it is hoped that the researches in this subject will be continued and that valuable information for the engineer in practice derived from them.

CONCRETE TESTS—COMPRESSION.

Proportions by weight: 1 part cement, 2 sand, 4 stone.

THEO. DENIS.
CARL REINHARDT.
G. G. HARE.

McGill University, April, 1896.

New machinery has been put in position at the cement works of the Rathbun Company at Napanee Mills, and the output of the mills will be greatly increased.

A series of lectures on bridge designing has recently been delivered before the Applied Science Graduates' Society of McGill University, by Mr. J. A. L. Waddell, M. Am. Soc. C. E., a graduate of the civil engineering school of McGill, now of Kansas City, Mo.

The following are the newly appointed examiners of the Province of Quebec Association of Architects for the term commencing January, 1897: Messrs. Chas. Baillargé, F. X. Berlinguet, J. F. Peachy, of Quebec; Stewart Henbest Capper, Professor of Architecture at McGill University; A. T. Taylor, F. R. I. B. A., and Jos. Venne, of Montreal.

At a recent meeting of the governors of McGill University, Mr. R. J. Durrey, B. Le., A. M. G. C. E., London, was appointed assistant-professor of mechanical engineering in the faculty of applied science, in the place of Mr. J. G. Guest, who resigned a short time ago to accept the position of professor of mechanical engineering in the School of Engineering at Worchester, Mass.

CONVENTION OF THE ONTARIO ASSOCIATION OF ARCHITECTS.

THE annual convention, which will this year be held on Jan. 12th and 13th, will devote itself more than hitherto to artistic criticism in the form of free discussion of representations of executed work thrown on the wall by means of a stereopticon. Besides the usual display of members' work by this means, it is proposed to discuss the best examples of old work in Toronto; and there is talk of substituting for the paper that has always hitherto been given by some member of the staff of the School of Practical Science, a similar display of examples of some one style, selected from the admirable photos taken in England by Mr. Jos. Keele for the School collection of architectural photographs, and accompanying the exhibition by comment and discussion. There will also be two papers, one from Professor Capper of McGill University, of which the title has not been received, and one from Mr. D. B. Dick, on the "Possibility of a New Style." The programme seems to have a practical tendency all through, and will probably bring out further the more sociable manner of carrying on discussions that was noticeable at the last convention.

THE DUTY ON ARCHITECTS' MATERIALS.

A DEPUTATION representing the Ontario Association of Architects, interviewed the Tariff Commissioners on the occasion of their last visit to Toronto, with the object of endeavoring to secure a reduction in the duties on materials used by architects.

The following letter, expressive of the views of the Association, and accompanying memorandum, were placed in the hands of the Commissioners by Mr. Langton, the Registrar:—

"The accompanying statement of the duty imposed upon materials used by architects states also to what extent these materials are manufactured in Canada, and shows that, although there are two of the articles made in Canada, it is only imported articles of that kind that are used by architects. So that it is true to say that upon all the drawing materials used by architects there is a duty of from 25" to 35", and that none of these articles are manufactured in Canada.

"The duty, therefore, is of no use except as a contribution to revenue; and while regarded as a contribution to revenue, the result must be small, because the architectural profession comprises but a small body of men, to each architect the addition to his office expenses caused by these duties is of considerable importance.

"Nor is this a case where the tax levied on one body of men can be transmitted to others in the way of charges. An architect's fee is fixed by custom as a commission on the cost of the building erected; his own expenses do not enter into the calculation, and though they are greater under this tariff than before, there is no customary method of adjusting his charges to this increase."

STATEMENT CONCERNING ARCHITECTS' MATERIALS.

Tracing linen	Duty	7½%	Not made in Canada.
Prepared tracing paper	"	35	" " "
Black print paper	"	35	The composition a chemical secret known only to two persons in the U. S., and made by them.
Blue print paper	"	35	A little of this made in Canada, but the duty does not protect its manufacture, because the drawing paper which forms its base must be imported from the U. S. under duty. In the U. S. both the paper and process are native, and the manufacturers are able to keep the Canadian market.
White drawing paper	"	25	Not made in Canada.
White tracing paper	"	25	" " "
Manilla paper	"	25	A little made in Canada, but not of a quality suitable for our use. What we use is imported.
Inks			
Colors	"	23	Not made in Canada.
Instruments			

A writer in an exchange warns painters not to mix chrome yellow with Prussian blue to produce a bright green. Either substitute ultramarine for the Prussian blue, or yellow ochre or raw sienna for the chrome yellow.

POINTS ON VENTILATION.

SINCE a man inhales on an average 16 ft. to 18 ft. of air in an hour, and the air he exhales contains 180 times as much carbonic acid as fresh air, it will require 120 times as much fresh air to dilute it sufficiently in order to render it suitable for respiration. Each individual will require, therefore, about 2,000 cubic feet of fresh air per hour.

In practice it is generally found that a larger quantity is desirable, and this is usually stated at 3,000 cubic feet. Since the air of a room, it may be said, is not changed more than three or four times an hour, it is desirable that, if each individual is to be provided with 3,000 cubic feet of fresh air per hour, he should have an air-space of from 750 to 1,000 cubic feet.

It has been found that where a current of air enters a room at a greater rate than 2 ft. per second, a draught is caused. The art of ventilation, therefore, may be described as the art of supplying a public building or dwelling with air at this rate, and in quantities sufficient to prevent the possibility of the carbonic acid from increasing beyond the limits of purity.

BRICKS MADE FROM SAND.

AN organization has been incorporated in San Francisco, California, which proposes to expend $50,000 in the purchase of a site and the erection of buildings for the manufacture of bricks from sand. The stone brick which it is proposed to make will be manufactured from powdered stone or the elements contained in stone, such as sand, clay, etc. These substances are mixed with a prepared "flux," which acts as a bond, holding together the particles of sand or other material used as a filler, the whole being thoroughly annealed by heating.

Among the advantages claimed for the brick is the saving of time, only ten hours being needed for their manufacture, instead of eight to thirty days; a much less consumption of fuel; scarcely any loss from burning; a crushing strength from 10,000 to 40,000 lbs. to the square inch instead of from 400 to 4,000 lbs., and a reduction of cost to three-fifths of that of the old style bricks.

TESTING QUICKSAND.

SUPPOSE we take a certain quantity of quicksand, dry it artificially, and then try to make it into quicksand again. Put it into a box and pour water on it carefully. Instantly the water is soaked up, and if we measure the volume or better, the weight of the sand, we shall see that it takes up a quantity of water that measures 30 per cent. of its own volume, or 20 per cent. by weight. The rest stays above the layer of sand. If we now pierce a little hole in the bottom of the box, we shall see pure water run out; the sand forms a kind of immovable filter. Also by turning the box upside down to see the sand keep its form like a stopper. It follows from this experiment that we cannot obtain quicksand in this way. We must reverse the condition of the experiment. Let us put the water into a vessel and sift in the dry sand in a thin stream, while shaking the vessel lightly. Then we shall get the thick but easily flowing compound known as quicksand. That the mixture may keep its mobility, two conditions are necessary: (1) The quantity of water must not be less than 21 per cent. by weight. (2) The whole must be continually though lightly shaken. If we increase the proportion or interrupt the agitation for an instant, the mass settles down, retaining about 20 per cent. of water, while the surplus, if it exists, rises to the top. La Nature.

CORRESPONDENCE.

[Letters are invited for this department on subjects relating to the building interests. To secure insertion, communications must be accompanied by the name and address of the author, but not necessarily for publication. The publisher will not assume responsibility for the opinions of correspondents.]

THE CONDUCT OF EXAMINATIONS.

TORONTO, Dec. 10, 1896.

To the Editor of the CANADIAN ARCHITECT AND BUILDER.

DEAR SIR, — Your correspondent, Mr. Ireland, in the November number of the CANADIAN ARCHITECT AND BUILDER expresses a wish that intending architects should be examined by "an independent and recognized public body." The Board of Examiners of the Ontario Association of Architects is in reality such a body; but being composed chiefly of architects it is possible to assert that is not independent, and perhaps Mr. Ireland means to do so.

The conduct of the examinations was given to the Association by the legislature along with limited public powers. When it was proposed to increase these powers the legislators who expressed themselves as favourable to doing so did not think it necessary to alter the present manner of conducting the examinations, although the Council suggested that the government should take the examining out of their hands. If it should be proposed to put the examinations in the hands of the government, the Association will be not only content but glad.

Yours truly,

W. A. LANGTON, Registrar.

THE ONTARIO ARCHITECTS' ACT.

To the Editor of the CANADIAN ARCHITECT AND BUILDER.

SIR, — In your November number Mr. S. J. Ireland's letter was to me a great surprise — a double surprise in that Mr. Ireland should not have been more familiar with the workings and aims of the Ontario Association of Architects, and that he should also be so unfamiliar with the qualifications for architectural practice.

As regards the O. A. A., Mr. Ireland wishes we had "an independent and recognized public examining body"; is he not aware of the fact that such a body has existed for several years — a body as independent as that of the legal, medical or clerical professions, and a body of recognized ability, composed as it is of the best men in the profession in Ontario; and even now for membership the O. A. A. makes it compulsory to pass certain examinations, and hard ones they are, comprising infinitely more than Mr. Ireland enumerates as necessary. This examining body and these examinations will continue after the amended Bill is passed, and all embryo architects will have to prove themselves for admission just as they have now — justice, of course, demanding that practising architects be admitted without examination.

Personally, I thank Mr. Ireland for bringing out these points against us. He states them as public opinions; I know they are public opinions, for I have repeatedly heard the same lines of argument, and I sincerely wish that the public understood our Bill, understood our workings, understood our history; if they did, there would not only be no dissenting voice, but they would favor us. We are not working for self, but for our art, and by forcing our would-be exponents to be properly qualified, we are doing a great good for Ontario architecture — a good that will be felt for all time.

In regard to our education, I must take issue with Mr. Ireland on every point, because the system of education in use by the O. A. A., and proposed to be continued under any additions to our Bill, is the best possible under present circumstances requiring five years' study in an office with three examinations, or graduation at the School of Science with three years in an office and one examination. To this the only advisable addition would be that five year office students should, during the fifth year, attend the School of Science to receive a polishing off in theory.

Mr. Ireland's contention in regard to a boy and divinity is proper for divinity, but if he would analyze architectural and divinity qualifications he would find that the boy, were he never at a church service, never heard a public speech from his birth till his graduation as a preacher, would be of no use in a pulpit; the school simply teaches him the laws and history; his own observation of church services alone will fit and experience him to stand in the pulpit. So also in architecture, which is largely a profession of observation and experience, the boy learns theory at school or studies it up for himself, and can only gain practising knowledge by several years' actual office work.

Mr. Ireland says his school will teach a boy in two years as much as we will learn in five in an office; well perhaps. Our offices must be funny places, for gloomy indeed is his picture of our fledglings wearing out five long weary years of their tender young lives in office drudgery, and especially foreboding is the information that after all this slavery they might have acquired as much or more knowledge in two years at an art school. I can assure Mr. Ireland that his ideas, as stated, in regard to office training, are entirely erroneous; if a youth enters a three-year office term a Science School graduate, he starts with a certain quantity of knowledge that the other lacks, who, not a graduate, takes the five-year term, which extra two years are added that he may pick up as fully as possible what the Science School one knew upon entering, and the office history of the boy runs through the whole gamut, from ignorance to proficiency, from tracing and copying during the first few months to preliminary sketches, perspective rendering, original drawings, details, designing, writing specifications and superintendence, besides becoming thoroughly familiar with all classes of materials. Five years of this in a good office will turn out a tolerably fair architect if the boy be any good. Now to this we add the O. A. A. requirements of three examinations, thus forcing the boy to systematic study and giving him a thorough test, proving that he can build strongly and well and that he is master of his materials. What more can the public demand, and are they not aware that we have been doing this very thing for several years?

We do not require to alter our Bill all that we require is that the public throw off the shackles of deliberate blindness, study our aims, and they will grant our requests.

As one who has passed the O. A. A. examinations, I cannot urge too strongly upon all the boys to study, and study hard and pass the examinations, whether or not they intend ever to practice in Ontario; and to those who intend entering the profession, if their purse strings will admit it, I strongly advise graduation at the School of Science before taking the three-year term which is then allowed, and don't enter the lists unless from pure love of architecture, and in return the O. A. A. welcomes you.

DAVID GUNN BAXTER.

STRATFORD, Dec. 4, 1896.

ILLUSTRATIONS.

PRELIMINARY SKETCHES FOR PROPOSED STABLE AND COACHMAN'S DWELLING AT OAKVILLE, ONT.
MESSRS. DICK & WICKSON, ARCHITECTS.

REPRODUCTION FROM A DRAWING BY N. T. LYON, OF CENTRAL PORTION OF A STAINED GLASS WINDOW, PRESENTED BY ARCHBISHOP WALSH TO THE CHAPEL OF THE SISTERS OF ST. JOSEPH, TORONTO, OF WHICH MR. JOS. CONNOLLY IS THE ARCHITECT.

RESIDENCE FOR MR. W. R. MILLER, STANLEY STREET, MONTREAL. R. FINDLAY, ARCHITECT.

This residence, recently completed, is a good illustration of what can be done in making an old building meet modern requirements, and by the skill of the architect such changes are often successfully carried out.

The old building, once a private stable and coach house, and belonging to one of Montreal's leading citizens, was purchased by Mr. Miller, who decided to convert it into a residence, and entrusted the work to Robt. Findlay, architect. The result has been most satisfactory, and the building is now considered one of the best residences in the city. Although so great a change has been wrought, the old foundations, a portion of the old walls, and the entrance doorway, still remain, and form part of the new building. The interior is handsomely designed and finished in the old colonial style. A handsome stable and out-buildings have also been erected within the grounds. The site is an excellent one on the mountain slope and overlooking the city.

FRENCH METHODS OF CONSTRUCTION.

IN the construction of large buildings in France iron has been used to a much less extent than in America. Heretofore its use in its ordinary form has been confined to floors, partitions and roofs, where, as a rule, it is covered by a coating of cement, wood or stone, except in the case of buildings destined for brasseries or drinking halls, where the iron was left visible, and emphasized by means of painting or mosaic work. In the city of Paris, however, iron is fast finding favor for employment in combination with other materials, such as cement or concrete, and in a special form known as the cement arme system. By this method iron and steel is employed in the form of thick wire, trellis, or light bars, imbedded in cement or concrete. Three different systems of this construction have been used in various buildings of more or less importance, and are said to possess advantages when employed for floors, partitions and roofs, both as regards economy, conveniences for internal arrangements, and decorative purposes.

In a building constructed for the Society of Civil Engineers, iron and other modern materials were liberally used. The facade in this building is 100 feet long, and is built of solid stonework, the thickness of the masonry at the lower storeys being 24 inches and at the upper stories 18 inches. The body of the building is constructed of a framework of iron, the chief supports consisting of four framed iron uprights, 16 in. by 16 in., rising from the basement to the roof. The uprights are held together at the floor by iron girders, supporting the iron joists of the upper floors and the light partitions which divide up each storey.

Nearly all the stone is dressed after being put in place, which affords greater facilities for studying the general ensemble of the facade and the proper scale to be given to the mouldings and decoration. The stone is soft when first taken from the quarries, but becomes hard and durable after dressing and exposure to the air. The courtyard wall of the building is formed of light brick or metallic fillings between the iron uprights and the party walls.

The ground floor is built after the Coignet system, composed of light iron bars and cement; the first floor and its supporting pillars and arches are constructed after the Hennebique system of cement arme.; the upper floors are formed of iron joists filled in with light supports and plaster or with terra cotta fillings between joists.

The ground floor of the conference hall, 30 x 20 ft., paved with mosaic work, will be a movable one, to be raised or lowered by an ingenious system of hydraulics, and capable of being placed in an inclined position for conference meetings or raised to a horizontal position for ball-room purposes.

The roof is lined internally with agglomerated cork bricks, and the walls of the area will be lined with opaline, a vitreous material of a bluish-white color, which will afford cleanliness and afford additional light.

ELECTRIC STONE CUTTING.

AN ingenious application of electricity has recently been made in the large new Hotel Cecil, in London, Eng. After the marble staircase was put up it was found that the balusters had been placed so far apart that it was quite possible for a child to slip between them. In order to make the stairs perfectly safe it was resolved to place a brass baluster between every two marble ones. In order to do this as quickly as possible, with a minimum of noise and dirt, the use of an electric motor with flexible shaft and twisted drill was suggested. A small one-horse iron-clad motor, controlled by the operator, was used, and the holes were drilled at the rate of thirty or forty a day. They were neat and clean, with very little fracture at the edges. This method of rapid drilling is said to be likely to take a prominent place in marble working.

RECENT CANADIAN PATENTS.

The following patents, of interest to architects and builders, have recently been granted for Canada:

Hot Water Boiler — Geo. C. Morrison, Hamilton, Ont. The claim is for a vertical boiler, constructed of one seamless tubular piece having threaded or screwed ends, and faced in combination with the heads, having inner true faces to engage with end of said boiler when screwed in position, with water inlet and circulating tube or pipe, and a water heating reservoir connected by means of pipes.

Clay Mould for Sanitary Ware — F. B. Dakin, of Iberville, and C. C. Corneille, of Montreal, Que. It consists of a clay body, comprising Pennsylvania Feldspathic clay as a base, a silicious clay, English ball clay and English Cornwall stone.

Brick Kiln — John K. Caldwell, Minneapolis, Minn.

Rock Crushing and Grinding Apparatus — Kinkead Mill Company, San Francisco, Cal.

Hot Water Heater — John Barsley, Montreal, Que.

Hydrant — E. S. Manney, Montreal, Que.

Hot Water Furnace — Joseph T. Robbins, Newton, Iowa.

Metallic Lathing — Mex. R. Fordyce, Newark, U. S.

Metal Lath — D. B. Hilton, Brooklyn, N. J.

Brick-Making Machine — Frank Gutteridge, Seaforth, Ont.

Art or Process of Making Stone for Buildings — R. A. Pyne, J. M. Hutchins, Z. Hemphill and H. M. East, of Toronto.

Machine for the Production of Slabs of Plaster, Cement or Composition — R. W. Hitchins, Finsbury, London, Eng.

THE INFLUENCE OF STEEL CONSTRUCTION AND PLATE GLASS UPON STYLE.*

THE author of an article recently published in Lippincott's Magazine summarizes the laws of architectural design in the sentence, "form follows function," and endeavors to condense into three words what others have vainly tried to enunciate in numerous treatises and in bulky volumes on the Philosophy of Art. If it was necessary to state in a three-worded aphorism the entire law of architectural design and composition, nothing could have better suited the purpose than the words quoted above from the pen of that clear thinker and brilliant writer, Louis H. Sullivan.

Every architectural work has a "function," a purpose which has called it into being, and its success is measured by the degree of approximation to fulfilment of "function" which characterizes its "form."

From this one might infer that it is only necessary to divide into a few classes the functions to be served by architectural structures, and to determine the form best adapted to each, and thus develop an infallibly correct system of architectural design from which none may deviate without incurring the reproach of ignorance and lack of culture.

We should then have an architecture somewhat more scientific and vastly more practical, but as trite and as devoid of the interest imparted by the creative impulse as is the architecture founded upon the principle, form follows historic precedent, which stamps as barbaric every structure for which the architect has failed to provide an academically and historically correct mask and costume, and which treats as heresy an attempt to do, not as the Romans did in the year 1, but to do as one thinks the Romans might have done in the year 1896.

Returning to Mr. Sullivan's aphorism, we find that he bases it upon studies and conversations of nature which, carried a little farther, show that although the common function of all organic creation is maintenance and propagation of the various species, yet an ever varying environment has produced an infinite number of species and innumerable differences in individuals of each species.

Therefore, if "form follows function," it does not follow in a straight line, nor in accordance with a simple mathematical formula, but along the lines of curves whose elements are always changing and never alike.

If the lines of development and growth of vegetable and animal organisms are infinitely differentiated, the processes of untrammelled human thought and human emotions are even more subtile in the differences and shading of their manifestations, while the natural variations in conditions of human environment are as great as those which influence the developments of form in the lower organisms; and human work is further modified by necessary artificial conditions and circumstances.

Therefore, before accepting Mr. Sullivan's statement of the underlying law upon which all good architectural design and all true architectural style is founded, it may be well to amend it, and say: "function and environment determine form," using the words environment and form in their broadest sense.

The functions served by the work of the architect have expanded but little, and have varied still less within the limits of the historic records of architecture; nor has there been much change until the last quarter of this century in those conditions of environment which comprise the structural and decorative materials at the disposal of the architect.

The great epochs in the development of architectural style are respectively characterized by the introduction of the pointed arch and its characteristic vaultings. It is our good fortune to have inherited all that was accomplished by the many generations who lived and thought and worked in these epochs. We are still more blessed in being allowed the privilege of participating in the creation and in witnessing the birth of another epoch in architectural design, the form of style of which will be founded upon the discovery of the steel pillar, the steel beam, the clear sheet of plate glass, electric light and mechanical ventilation—all devoted to the service of functions or wants created by the greater intensity of modern life and by improved means of communication between places and men.

Probably there were those in Greece who deplored the departure from correct and historic Assyrian and Egyptian architecture which had to be made in order to originate and establish the most exquisitely finished and most fully and logically developed architectural style the world has known. And when the sturdy but gross-minded Roman used and modified Greek prototypes in accordance with his coarser and more aggressive mentality, and when, finally, he introduced the arch and the vault, and substituted for the refined and elegant treatment of the severe and regular forms inseparable from beam and lintel construction, a bold and comparatively unrefined treatment of the more irregular and picturesque forms made possible by the discovery of the arch, the new departure was certainly as displeasing and distressing to the purists and scholars of that day as were in latter days the works of those alleged barbarians whose efforts to utilize to the utmost the means and knowledge at their command, created the styles known as "Byzantine" and "Romanesque," and finally that culmination of protest against dry-as-dust tradition, the styles which scholars and men of culture derisively named after the barbarian Goths.

So, also, in our day, many of those who have been taught to understand and love and honor forms and traditions transmitted from past ages shrink from contact with the new materials and processes, and, noting the inevitable modifications of time-honored theory and practice, lift their voices in protest against legitimizing forms which are the offspring of newly-arisen functions and of newly-discovered conditions of environment.

And yet each historic style was called into being in obedience to new developments of function or environment, and each was in its day an iconoclastic innovation upon well established and firmly founded practice.

Therefore we are justified in assuming that the new conditions will exert a marked influence on architectural style in our day and in the future.

It is the duty of those, who by familiarity with the historical styles are best fitted for this task, to ascertain the creative principles and laws which underlie the architectural style of by-gone periods of greatest artistic achievement, and to apply these principles to the utilization of the means placed at the disposal of the architect of our day for satisfying the requirements of the day.

The American architect, who travels in Europe and studies the architecture of the many ages which have preceded the last century, is impressed and charmed by the freedom and naïveté with which consciousness of the fact that each age is the heir of all preceding ages is proclaimed in the composition and in detail of so many structures. Nothing can be more interesting than the observation of the existence of a living vigorous style, joyous in the consciousness of life, free to assimilate the old and to create the new. Nor is it unprofitable to follow a style from the exuberance of its youthful vigor to old age and decadence, to ossification and crystallization into an inert and lifeless set of fixed and unalterable rules, into a fetich to be worshipped by future generations; in other words, into an academic historic style.

But after one has taken it all in, there is one impression stronger than all others. It is the consciousness of the zeal and earnestness of the all-pervading endeavor to so utilize all the means at command, that the form and expression of each structure might conform to its function, whether that were the worship of God or the glorification of guild or municipality; whether intended to serve the lavish display of the wealth and dignity of the great noble, or to house the humble burgher, each kind of structure has its individuality, and of these, again, each gives expression to the character and personality of its occupant.

Our generation has in many ways shown itself worthy of its heirship of so many ages, and has given expression to its appreciation of its good fortune by transmitting to the future an inheritance still more valuable than that which has fallen to its lot.

What can the architect do, that he also may prove himself worthy of opportunities so much greater than those enjoyed by his predecessors?

Human nature has limitations which circumscribe and define the attainable in literature and art. There will be none greater than Homer, than Moses, than David, than Shakespeare, than Phidias, than Leonardo da Vinci, than Raphael, than Michael Angelo; no author, no sculptor, no painter, no architect can as an artist expect to excel many who have gone before. But the architect is not only an artist, but also an engineer, a man of science and a man of affairs. In these latter capacities, the architect of to-day has at his command instrumentalities and opportunities unknown to his predecessors. Were he an artist only, the giant strides which science, and by its aid industry, communication and traffic have made in the past fifty years would leave him by the wayside, content as are his fellow-artists of the brush and chisel to admire the onward rush, to be with it, but not of it, to be dazed by its splendor and to thrive and wax fat under the patronage of those who initiate and control the movement of modern material progress.

*Paper by Mr. Dankmar Adler, presented before the American Institute of Architects.

But architecture is not permitted to remain placidly contemplative of the march of events. The architect is not allowed to wait until, seized by an irresistible impulse from within, he gives the world the fruit of his studies and musings. He is of the world as well as in it. The world of to-day has greater need of his aid than had any previous period, and he is pressed into its service and must work for it and with it, no matter whether or not urged by the spirit within him. The world must have buildings; it will have them adapted to its wants and functions; it will insist upon the utilization of the best of the materials and processes which scientific and industrial progress place at its disposal. The architect must, therefore, fit himself for the duties thrust upon him. The world calls upon him to do the work of to-day with the tools of to-day, not as a tyro, not as one who must first learn how, but as an architect, a master worker, as one of whom the world believes that familiarity which he has acquired with the processes by which the work of other periods has been accomplished makes him better fitted for the work of to-day, and that he will press into its service all the experience of many ages and epochs.

Michael Angelo was painter, sculptor, architect, diplomat, but above all, and in all, an artist. An important factor in his greatness as an architect was his familiarity with the technique of the auxiliary and subsidiary arts, sciences and crafts, the command of which devolves upon the architect. The great Buonarotti did not disdain to learn the metal-founder's, the quarry-worker's and other crafts in order to be the better able to carry out the plans which his great mind had conceived. Were he among us now, he would be in the front rank of the experts and specialists in all the modern arts and sciences which have arisen to perplex and worry the artist-architect wedded to the traditions, processes and materials of the past. And being Master of specialties and details, he would, as General, master them all into martial array for overcoming the difficulties incident to the expanded and diversified demands which our time makes upon the architect.

Few, perhaps none of us, can be equal to Buonarotti, but all can emulate him in his zeal and capacity for hard work. We, too, can become impatient and contemptuous of the performance of auxiliaries and specialists, and dismissing them, can ourselves acquire a knowledge of the technique of their arts and sciences and crafts, and in the furnace heat of zeal and enthusiasm for the attainment of a great end, combine all that we honor in the lore and traditions of our profession with the discoveries and achievements of the science of to-day, pour all into the mould of contemporary requirements and bring forth our contribution to the architecture of the New World, the new age of steel, electricity and scientific progress.

For several years it has been the fashion among the professors of our art to decry the new materials and processes of construction, and condemn their most noteworthy applications to the service of requirements born of modern conditions. The contributions which modern science has made to our power to command and utilize the materials and forces of nature, and the increased and expanded opportunities for the creation of useful and beautiful works which modern society has given us, have been looked upon askance. And it is greatly to be regretted that some of those whose works had proved them well qualified to determine under the new environment the forms best adapted to the old, as well as the new functions, have been most persistent in their condemnatory utterances against the new problems which they themselves were so successfully solving.

What I have written is intended to be a protest against the dogma that art in architecture ended with the Renaissance, a denial of the assumption that the uses of materials and processes, and wants and functions unknown to the masters who flourished in that glorious period, or their predecessors in other eras of great artistic vigor in architecture, is incompatible with the performance of truly artistic work.

I wish to maintain that the steel pillar and beam, and other contemporary contributions to the materials and processes of building construction, that the modern business building, and many other so called monstrosities, are as legitimate contributions to architectural art as were in their day, when first introduced, the stone pier and lintel, the brick wall or pier, the arch, the vault, the roofed temple, the vaulted basilica, the spired and buttressed cathedral. All that is wanting is the will and the ability to make proper use of these newly discovered agencies.

The new materials and processes, the new requirements, should not, however, in their introduction into architecture and in their assimilation by our art, be treated as things apart and by themselves, but they should be treated as related to and part of all that has gone before in the long history of human and artistic progress.

The author of to-day has at his disposal and does not disdain to use an enlarged vocabulary; the musician has a greater range of instruments, a richer and fuller orchestration; and the great composer deems it a privilege to be able to evolve combinations of tone that were unattainable to his predecessors. And even if the painter of to-day uses the same pigments, and depicts the same phases of animate and inanimate nature, and the sculptor uses the same marble, and both painter and sculptor play upon the same gamut of human emotions, as did their prototypes for many generations, that is no reason why the architect should look askance upon new instrumentalities and new opportunities for developing and enlarging the scope of his art.

Let us, then, welcome the prosaic output of furnace and mill, and even the unpromising and garish sheet of plate-glass. If they are always used where they are wanted and as they are wanted and never where they are not wanted, nor as they are not wanted, we shall have taken the first step towards the transmutation of these utterances of scientific prose into the language of poetry and art. In the nature of things, the block of rough stone, the lump of clay, the log of timber, are all apparently as uncompromisingly unpoetic and inartistic as the much degraded and unappreciated modern intruders into the programme of architectural composition, which form the title of this paper. What they have of poetic suggestion and significance they owe to the genius of man, and what man has done, man can do. Let us not stand back and admit that we are unable to learn from our predecessors how difficulties are overcome, how victory is wrested from apparent defeat.

Yet another word. I have quoted the dictum "form follows function," and have modified it into the words "function and environment determine form."

Steel pillars and steel beams occupy so little space that in order to enclose structures of which they are the essential supporting parts, they must be furnished with a filling, if a space enclosing structure is to be erected, and steel posts and beams to be adequately protected against possible attacks of fire must receive bulky fire protective coverings. In these fillings and coverings we obtain media for artistic treatment which may be handled solely with reference to the desire to adapt "form" to "function."

From this I deduce that the influence of the new materials and processes will tend to a more free and less trammelled treatment of architectural design, and that the striving for the creation of ideally perfect form will be less hampered by limitations incident to the use of refractory materials of construction.

PERSONAL.

The death is announced of Mr. J. C. Clements, contractor, of Vancouver, B. C.

C. A. & E. W. Barber, architects and mechanical engineers, have opened an office at Rat Portage, Ont.

The firm of J. W. & E. C. Hopkins, architects, Montreal, has been dissolved, Mr. J. W. Hopkins continuing.

At the recent convention at Chicago of the American Society of Municipal Improvement, Mr. E. H. Keating, city engineer of Toronto, was elected a member of the Water Works and Water Supply Committee.

Mr. H. D. Ellis, formerly of the city engineer's staff, Toronto, has lately returned from Manitoba, where he has been engaged in the construction of 100 miles of railway from Gladstone through the Dauphin district to Lake Winnipegoosis.

Mr. E. C. Hopkins, formerly of the firm of J. W. & E. C. Hopkins, architects, Montreal, has recently formed a new partnership with Mr. E. Sainbault, certified architect, of Paris. The new firm will be known as Hopkins & Sainbault, with offices at 1,586½ Notre Dame street, Montreal.

Messrs. Heney and Borthwick, of Ottawa, have taken suit in the Exchequer Court for $15,000 for work done in connection with the construction of a drain at the Lachine Canal.

Action has been taken by Messrs. Blanshard & Norton, brick and stone contractors, against the trustees of the First Methodist Church, London, for a balance of about $7,000. The trustees claim to be holding back part of their contract price on account of the mechanics' liens placed by a sub-contractor.

STUDENTS' DEPARTMENT.

LEAD, COPPER AND ZINC FOR ROOFING.*

In attempting to compare the relative claims of each of the three metals lead, zinc and copper—as materials for roof covering, one has first to consider what are the chief requirements for a material used for this purpose.

These may be stated in the following order: First of all, durability; then lightness; then workableness; next, capacity to resist fire; and lastly insonorousness.

Although the question of durability must be decided chiefly by experience and observation of special instances, yet something may be predicted as at least highly probable from a consideration of the texture of the metal and its liability to corrosion from acids, etc. Into this inquiry, of course, the element of weight largely enters, and I therefore take the opportunity of naming specific gravity and atomic weights of each of the three metals:

	Specific Gravity.		Atomic Weights.
Lead	11·4	Lead	207
Copper	8·8	Copper	63·5
Zinc	6·9	Zinc	65

or, taking the weight of a superficial foot 1-16 in. thick we find it

Lead	about 3¼ lbs.
Copper	" 2¾ "
Zinc	" 2¼ "

Thus, if weight were the only consideration in this inquiry as to durability, lead would be nearly twice as durable as zinc and at least a third more durable than copper. But there is another element which must be equally considered namely, the hardness or, rather, firmness of the material, and perhaps this property can best be indicated by the relative amount of conductivity, which in lead may be represented by 230; nearly twice as high in zinc, say 430; while in copper it is more than twice as high as zinc and more than four times as high as lead, viz., 1,000.

And the conclusion which we might derive from these figures is corroborated by those which represent the fusibility of the different metals, viz., lead, 630 deg. Fahr.; zinc, 800 deg. Fahr.; and copper, nearly four times that of lead and nearly three times that of zinc, viz., 2,143 deg. Fahr.

It thus appears that though lead is so very much heavier than the other two metals, its want of firmness is still more conspicuous, and, on the whole, roughly it might be guessed that lead and copper would, surrounding conditions being equal, be of about equal durability, particularly as neither of these metals is easily acted upon by acids.

As to zinc, although it occupies a middle place between lead and copper, both in the matter of weight and also of firmness, it is yet quite out of the competition as to durability from the fact that acids act upon it with great facility.

The softness of lead has its advantages, since it is easy to use it of great thickness, while at the same time the low price makes it possible to do this without a prohibitive outlay; so that lead may be laid of a thickness weighing perhaps 6 lbs. or 7 lbs. to the foot as easily as copper weighing only 16 oz. or 18 oz. to the foot. And at these relative weights it would be fair to assume that the metals would be about equally durable. Experience endorses these assumptions, and it is found to be practically the case that zinc, laid of the best thickness which it is worth while to use, say about 1½ lbs. to the superficial foot, will keep a roof sound from twenty to thirty years, while copper of 16 oz. to the foot, or lead of 7 lbs. form either of them a practically permanent covering lasting 100 years or upwards; that is to say, if properly laid and in favorable situations.

But the question of durability cannot be disposed of without a consideration of the property of expansion. When a zinc flat lets in water, and has to be taken up for renewal, it is often seen that the metal is not perished, but is split into cracks. The heat of the sun has so increased the size of the metal that, having been fastened by nails, or soldered together in large sheets, it has risen in buckles. When a shower of rain or a cold night has followed, the metal has contracted, and so caused the cracks. If the expansion of zinc is set down at 30, lead will show 28, and copper only 19.

In laying either of the metals care has to be taken to allow for expansion, and if the proper methods are adopted much can be done to prevent the injurious effects of it:

There is one thing to consider viz., the capacity to bear traffic without injury. Flat roofs are very likely to be walked over, and to have things placed upon them, round or under which dirt or moisture can collect. On account of its extreme softness, lead, unless very thick, is easily damaged by traffic; and zinc, although harder, is brittle, and is also easily corroded by foreign matter; and both, as already mentioned, are exceedingly liable to buckles and cracks. Copper, on the other hand, is so tough that it is practically uninjured by traffic and little liable to corrosion. It should, however, be laid with wood rolls and welted caps, and not according to the old method of stand-up welts.

So far for flat roofs. For pitched roofs and towers or spires the great weight of lead is much against its use. In such positions lead has a way of crawling down, as it is called, and this is a very destructive process and greatly shortens its usefulness. As an instance of this I may mention that some years ago we had an order to cover the spire of St. Peter's Church, Cornhill, with copper. It was then covered with lead, which we ascertained had been laid in the year 1804.

When the lead was stripped off it was found to be very thick—some of it at least from 10 lb. to 12 lb. to the foot, and was not perished, but was very badly torn and cracked through the expansion and contraction and the creeping down in some places, and the giving way of the wood supports in others. In fact, its own weight had destroyed it.

The copper which we put on in place of it would weigh perhaps not more than one-eighth or one-tenth of the lead, and would rather tend to support the woodwork than require to be supported by it. The key which forms a sort of finial on the top of the spire was in good repair and did not require renewal it was of copper. It is said, but I am not sure upon what evidence, that the lead on the roof of Bristol Cathedral crawled down as much as 18 in. in two years.

The extreme softness of lead makes it unfit for ornamental work. It is always necessary, when lead is being used, that the wood should first be formed into the shapes, and the lead dressed closely over these; on account of their stiffness zinc and copper do not require the mouldings and ornaments to be formed in the wood, but are sufficiently supported by a rough wood core. Zinc, however, suffers in the process of stamping and hammering, as it is seriously injured by application of heat.

Copper, on the other hand, may be heated to a red, or even a white glow, and then immersed in cold water without being in any way injured, but by this annealing, as it is called, is rendered soft and pliable, and regains its stiffness under the hammer or stamp.

On these accounts copper has come to be very much used for ornamental roofs and for spires, fleches, finials, figures, etc., for which it is also specially adapted on account of the little weight per foot which is necessary to use.

Lead has been so very largely used for roofs for many hundreds of years that it is unnecessary to quote instances as to its lasting power when properly laid on flat roofs, but as the durability of copper is not so well known, I may mention one or two examples.

The tower of the parish church of Hampstead was covered with copper in the year 1784, and the copper is still in good condition, being of a beautiful green color. Some years ago, however, in a severe gale, two or three of the sheets were blown off, and had to be replaced by new sheets, which, of course, have still the dark look. Mr. Clowser, a builder, of Hampstead, told us that his old father knew that the tower was covered with copper over 100 years ago, and the church records give the date above mentioned.

*One of a series of papers on "Roof Coverings," read before the London Architectural Association by Mr. G. Ewart.

A few years ago we had to replace a copper flat on the roof of Somerset house. The copper itself was not perished, as may be seen by the sample which we kept. The reason it had to be replaced was that it had been laid in the old style with stand-up welts, and these had been trodden down and broken. There is good reason to believe that this copper was laid when Somerset house was built.

We have also obtained a sample of the copper on the church of St. Botolph's, which is very thin, weighing only about 14 oz. to the foot. The metal is still not perished, although probably laid when the church was built. Through the sinking of the timber it is out of repair, and this is one of many instances in which the copper covering outlasts the material of the building. A remarkable instance occurred some little time ago, which showed, at the same time, the great durability of copper and the importance of having it properly laid.

We were instructed to take the old copper off a church in Wiltshire, and were told by the architect that it had been laid 250 years ago. The flat sheets were not perished, but the standing welts were worn through. We cut the worn edges off the sheets, and relaid the same material with wood rolls, after repairing the wood work, which had rotted where the upright welts had admitted water.

Next to this paramount question of durability comes that of weight, or, we should rather say, of lightness. Here, of course, lead cannot stand comparison with either zinc or copper. Lead is so soft, and has so little coherence, that in order to make a good job, it is found necessary to lay it very thick—nearly ⅛ in. But at the same time, lead is exceedingly heavy, so that a square foot of this thickness weighs upwards of 7 lbs.; it thus happens that when allowance has been made for the necessary rolls and laps, the lead necessary to cover a square of 100 ft. weighs rather more than the slates which would be necessary to cover the same area, and at least half as much as plain tiles.

Zinc, on account of its superior firmness, is laid in the best manner at about one-fourth of this thickness and less than one-fourth of the weight, say 1½ lbs. to the foot; but then, as already mentioned, zinc cannot be relied upon to stand more than about one-fourth of the time that lead will.

With copper, however, the case is different. Here we have at least equal durability to that of thick lead, with a thickness still less than that of zinc, and a weight of only 16 oz. to the foot.

On new structures, substantially built, the question of a few tons, more or less, upon the roof, is not, I suppose of very serious consequence. Yet, even in such structures, it may be often worth while to be able safely to use lighter timbers; but for an old roof, where the supports are not too strong, a few tons, one way or the other, may make a very great difference. I may quote as an instance the flat roof of the Portman Rooms. We found this covered with lead and leaking all over. In many places the woodwork had sunk, and to cover it with lead would have been exceedingly dangerous. But a perfectly safe and a perfectly sound job was made with copper.

It is unnecessary to add that as a covering to spires, fleches, domes and suchlike erections, the comparative lightness of copper makes it exceedingly appropriate.

Coming now to the next desideratum in a roof-covering, which, for want of a better word, I have been obliged to name "Workableness," I must explain that I mean by this the possibility of being turned up with moderately sharp angles and twisted over into welts. As already mentioned, all the three metals under consideration expand and contract with changes of temperature—though copper very much less than either zinc or lead—and therefore all require some arrangement which will leave them free to expand or contract without blistering.

And then, of course, the sheets have to be somehow joined together, and the joint is to be made, if possible, without solder. For it is found that the places where soldered seams have been made perish long before the rest of the metal is worn out.

Although lead is so soft, yet on account of its great thickness it cannot be easily welted, and requires large rolls. On the other hand, its weight and softness incline it to lie close even without joints—only then, of course, it is easily displaced. Zinc, being the most expansive of the three metals, and being also more brittle than lead, requires great care in laying, and the provision of very free play for each sheet, both at the ends and sides. On this account, many drips are needed. This is sometimes very objectionable on account of the increase in height.

Copper, on the other hand, expands so little that if wood rolls are used at the sides of moderately wide sheets, the ends may be safely welted together in considerable lengths, and so few drips are necessary.

At the same time, copper is so easily worked that welts are readily made, and may be used not only to connect the sheets in lengths but also to fasten them to the roll-caps at the sides, thus making a very firm and light covering. As a fireproof material, copper is immensely the best of the three metals.

As already stated, lead melts at 630 deg. F., and, therefore, in a fire is soon poured down in a terrible stream, more dangerous than even falling timbers or bricks. Zinc melts at 800 deg. F., and blazes brightly if thrown into an ordinary coal fire.

Copper requires a temperature of 2,143 deg. F. to fuse it, and retains its shape even at a white heat.

As an example, I may mention the instance of a tower in which the woodwork was entirely consumed, while the copper covering was left standing as a hollow cone, the flames and smoke having escaped by a hole in the top. Another instance illustrating this fireproof quality is that of Mr. Stedall's Mantle Warehouse, in Portsmouth. Here the copper roof was found intact after the fire, although the building beneath it was gutted; the copper sheets had, in fact, prevented the exit of the flames and stopped the spread of the fire.

The last property I named as required in a roof-covering was Insonorousness. Here lead has the immense advantage of its exceeding softness, and the same quality of softness makes it a non-conductor of heat.

For a long time lead was almost the only metal used for covering roofs, sheet zinc being practically unknown, and the high price of copper almost prohibiting its use for buildings where economy had at all to be considered.

The introduction of sheet-zinc about sixty years ago, and a great reduction in the price of copper during the last twenty years, have altered this state of affairs.

The change would have been greater still but for the fall which has at the same time taken place in the price of lead, partly on account of the improvements in the methods of separating the silver from it.

At the present market rates sheet zinc is, weight for weight, nearly twice the price of lead, and sheet copper, weight for weight, nearly three times the price of zinc, or about five times the price of lead. It is evident, therefore, that for temporary work sheet zinc is by far the cheapest metal covering, being properly used at one-fourth the thickness, while it is not quite twice the price of lead, and at the same time it has the advantage of lightness.

On the other hand, compared with copper, although it is not much more than one-third of the price, it requires to be laid at least half again as thick.

For a covering to permanent buildings zinc, for reasons already stated, is inadmissible; while copper and lead are perhaps about equally durable, so far as the metal itself is concerned.

Lead has the advantage over copper of making much less noise in driving rain or a hailstorm, but copper has perhaps still greater advantages over lead, being only about one-sixth the weight, being almost absolutely fireproof, requiring very little support in ornamental work, having only a little more than half the expansiveness under heat, and consequently requiring fewer drips. To which may be added its capacity for being easily welted, and finally the beautiful color which it takes on from a damp atmosphere after a few years of exposure."

THE BUILDER

[THIS DEPARTMENT IS DESIGNED TO FURNISH INFORMATION SUITED TO THE REQUIREMENTS OF THE BUILDING TRADES. READERS ARE INVITED TO ASSIST IN MAKING IT AS HELPFUL AS POSSIBLE BY CONTRIBUTING OF THEIR EXPERIENCE, AND BY ASKING FOR PARTICULAR INFORMATION WHICH THEY MAY AT ANY TIME REQUIRE.]

Hanging Doors.

In fitting a door the workman should take pains to have it clear the panel about one-eighth of an inch on one side only. It is best always to "fit" from the hanging stile side; that is, have the hanging stile fit close to the jamb, and let the space all show on the lock stile; and when it is hinged, the space should be divided, allowing 1/16" clear on hinge side and the same on the lock side. One sixteenth space is a liberal allowance and should never be exceeded, and is only permissible when the doors are to be painted. Hardwood doors that are finished in natural wood should not show nearly this much space, but the lock stile should be bevelled slightly to allow of its inner edge to leave the jamb without striking. A door should not bind on its hinges; when closed it should remain so, even if the lock-bolt does not enter the keeper, nor should it drag on the floor or sill, or bind in the frame at any point. A door properly hung is a "joy forever," but one that is eternally striking some point in the jamb, or striking at the top or bottom every time it is opened, is a source of irritation and a corruption of good morals. In adjusting the hinges for ordinary panel doors, the proper distance to place the butts is eight inches from the top to the top of the hinge, and ten inches from the floor to the bottom of the lower hinge. If there is a third butt required, as is sometimes the case, it should be placed a little nearer the bottom hinge than the top one, as most of the labor and stress falls to the lower hinge always, and if the third butt is carried down below the centre of the door, it relives the bottom hinge materially. The lock should always be placed with its top edge on a line with the lock rail, that is, of course, if the door is one having a lock rail. Sometimes, however, as in multi-paneled outside rails there are no lock rails, in which case the workman must so adjust his lock that the spindle for the knobs will be just two feet eight inches from the bottom of the door, this distance being the correct height to place the knobs or pulls. In case there is a lock rail in the door, and the stiles of the door are narrower than ordinary, a rim lock should be used, for if a mortise lock be employed it will necessitate cutting away the tenon of the lock rail to insert the lock, a process that would destroy the strength of the door at an important point. If the stile is the full width, 4½ inches, a narrow mortise lock may be used without doing much injury to the door, providing the door is well made and properly glued together. The spindle on which the knobs are fastened, should pass through the door and lock, exactly at right angles in every direction. Workmen are often very careless on this point, and their carelessness leads to trouble and annoyance as the roses cannot receive either the spindle or the knobs properly, and binding against the wood follows, and both knob and spindle after a time work loose or the lock breaks at the eye with the constant strain. As much care should be exercised in trimming a door as in hanging it, in order to make a good lasting and satisfactory job.

Repairing Roofs.

Just about this time of the year many house owners will be made aware that they cannot any longer defer stopping the leaks in their roofs. In a shingle or slate roof, little difficulty will be experienced in stopping the leak, but with a flat roof, whether covered with composition, tin or sheet iron, the trick of curing the defect becomes a serious matter, particularly if the roof is wet, as it is likely to be during the fall and spring months. It is well known that it is very difficult to solder tin or sheet iron when it is covered with moisture, and should there be any holes in the tin or iron while there is water or snow on the roof, and it becomes a necessity to stop the holes to prevent the leakage, do not attempt to solder the holes, but adopt the following method: Procure a piece of iron about three sixteenths of an inch thick of suitable length and width to cover the hole. Have a sufficient number of holes drilled in it to take No. 10 one inch screws. Countersink holes to take in head of screws. Take a piece of felt cloth; a piece of an old hat will do if you have nothing better; make it the size of the iron; soak the cloth in thick oxide of iron paint or white lead; place the cloth over the hole, then lay over this the iron and screw tight down to the roof. If water is running down the roof it may be held back by building a dam above the leak with putty, which will divert the stream until such time as the leak is repaired. A little varnish mixed with the paint will tend to make the cloth stick better at first. When these cloth patches become dry they answer better than solder, and will outlast the roof. If the flashings break away from a chimney or from a brick wall, they can be fastened by taking wire nails and putting washers on them to make the heads large and driving them through the tin into the mortar joint; then the tin can be plastered with a cement made by mixing dry sand with iron paint to the consistency of mortar; sand and paint makes an exceedingly good medicine when properly applied, for curing leaky roofs. If a leak occurs between wood and brick, or on a gravel or composition roof, a proper application of this cement will give instant relief. For repairing about chimneys this cement is unequalled. When a gravel roof is wet, it is evident it would be difficult to repair it, with paint cement or hot tar. Yet, if the roof leaks it is at this time the repairs are required. In such cases take the best Portland cement, mix with about one quarter of sand, and see that it is well mixed while in a dry state. Put in the mixture just enough water to allow of its working with a trowel—don't make as fluid as mortar—apply to the leak and "trowel" it well. As the cement will harden under water, the fact of the gravel and felt being wet will not affect its efficiency in the least.

QUESTIONS AND ANSWERS.

A CORRESPONDENT, living in Montreal, asks for information regarding "the weights of different kinds of roofing, floors, stud-partitions finished, outside walls, of wood, brick, and stone, etc.?" In answer to these enquiries, the only thing we can do is to give the weight per foot, per yard, or per square; and having these, it will be an easy matter to ascertain the weight of any given roof, floor, partition or wall.

Commencing with roofs, we find the authorities giving the following figures:

(1) Slate Roofs: The average weight of one foot of slate laid on a roof, is 7½ pounds (Kidder). If pine, hemlock, or spruce is used for roofing boards, one square will weigh, if green, 300 pounds; if half seasoned, 270 pounds; if dry, 250 pounds (Hodgson.) In a piece of roof ten feet square, making 100 feet, there should be five rafters not less than 2" × 6" × 10', each of these containing 10 feet of lumber, making a total of 50 feet, the weight of which, if dry, will be 125 pounds. This will then make the weight of one square of a slated roof, as follows:

Slate	750 lbs.
Dry roofing boards	250 "
Dry rafters, 2" × 6"	125 "
Total weight	*1125 lbs.
If we place building paper under the slates, we add for each square	15 lbs.
and to this may be added nails	4 "
which brings the total up to	1144 lbs.

Sometimes a layer of mortar is placed under the slates, the mortar being spread about ⅜ of an inch thick. The average weight of mortar so laid is a little over two pounds to the foot. This would add, say, 225 lbs. to the load, less 15 lbs. for paper which will not be required if mortar is used. The actual weight will then stand at

*1125 lbs.	
Nails	4 "
Mortar	225 "
Making a total of	1354 lbs.

In making calculations for the size of timbers to be employed to sustain a roof of any kind, wind pressure must not be overlooked as an important factor. A roof calculated to sustain any given load, and no provision made for wind-pressure, would come to grief with the first wind storm that struck it. The usual figures allowed to meet this contingency are 40 lbs. to the square foot, but, as a matter of fact, hurricanes, cyclones and tornados sometimes have a velocity of 100 lbs. to the square foot; but, roofs being sloping, rarely get more than a pressure of 40 lbs., which would add to the weight of the roof, under wind stress, 4000 lbs., making an actual total the bearing timber of the roof must resist, of 1354 + 4000 = 5354 lbs. per square. This, however, is not all, as provision must be made for rain and for snow. A slate roof should be made strong enough to resist a pressure of 10,000 lbs. to the square, or 100 lbs. to the square foot.

(2) Shingle Roof:—One square of shingles laid 5 inches to the weather, pine or cedar, will weigh, if dry, 125 lbs (Vogdes). According to Trautwine, it requires two pounds of 4-penny nails to lay a square of shingles; but we don't think this estimate is correct. In practice we have found that it takes a little more than 3 lbs. of nails to properly lay a square of shingles. Taking these figures as our guide, we find that the weight of a shingle roof, including roof boards, five rafters 2" × 6", and mortar laid under the shingles, to be per square:

Shingles	125 lbs.
Dry roofing boards	250 "
Nails for roofing boards and shingles	7 "
Mortar	225 "
Total	732 lbs.

To this must be added wind pressure, also weight of snow and rain. Many architects build their roofs sufficiently strong to resist a pressure of 90 pounds to the square foot, a resistance that will prove equal to any stress that may arise.

(3) Galvanized Iron Roofs:—According to Kidder, the weight of a square foot of No. 16 guage galvanized sheet iron laid on roof, is 4½ pounds: that would equal 425 lbs. to the square, including solder, nails and battens. About 25 lbs. may be added to or taken from this figure per square, per guage, according as the iron used is heavier or lighter. The other factors are the same as for a slate or shingle roof.

(4) Tar or Composition Roofs vary in weight according to the quantity and quality of materials used; they average, however, about 200 lbs. to the square, being somewhat heavier than shingles and lighter than slates. The wood and timber work to be the same as for other flat roofs.

(5) Tin Roofs are about one-third as heavy as galvanized iron roof covering as given in the foregoing, but the formulas for timber and lumber are the same.

(6) If a roof is covered with corrugated sheet iron, the weight will be about ⅓ more than it would be if covered with flat iron of the same guage.

(7) Roofing Tiles of the ordinary kind weigh 16¼ pounds to the foot, so that a square of tiling would weigh 1625 pounds. Other factors in the roof would be the same as already exhibited in slate and other roofs.

With these figures before him, from which many formulas have purposely been avoided, the intelligent workman will have no difficulty in determining the weight of any given roof formed of the materials specified in the foregoing.

The weight of inside partition walls that are formed by 2 × 4 scantlings, lathed and plastered on both sides, plastering done in three-coat work, is reckoned to be, when the plastering is "green" or wet, about 200 lbs. per yard of surface. This, of course, means both sides, or two yards, plaster measurement. When dry, it will weigh about ⅓ less, or 133 pounds. If the studding is 2 × 6, add six pounds to these figures, and if the partition is boarded on one side, but lathed and plastered on both sides, add 18 lbs. more to the yard, and if boarded on both sides and lathed and plastered on both boarding, add another 18 lbs., making a total weight of one yard of a 2" × 4" partition, lathed and plastered in three-coat work on both sides, as follows:

Lathed and plastered only	133 lbs.
Boarded on one side, add	18 "
Boarded on the other side also	18 "
Total weight per yard	169 lbs.

The weight of any partition may be obtained, approx-

imately, by first finding the number of yards in the partition one side only—and multiplying by the figures given. Example: A partition 20 × 9 feet what is its weight? We find the partition contains exactly 20 yards, superficial, taking one side of it only, as per rule; then 133 × 20 = 2660 lbs. Here we have 133 pounds the weight of one yard of a partition composed of 2" × 4" studding, lathed and plastered on both sides in three-coat work. 20 represents the number of yards, so we have 20 times 133, which gives a total of 2660 lbs.

If the work is only two-coat work, we deduct 27 lbs. from 133, making a constant of 106 lbs. Openings are to be allowed for in these calculations, and the presumption is that all the materials used are dry, and that the mortar is set and hardened. The weight of plastering on one side of a partition, or on the inside of main walls may be put down at 55 lbs. This does not include lath or studding.

A square yard of a wall formed of 2" × 4" scantling, 1" boards, a layer of building paper, half-inch clapboards, lapped, and lathed and plastered inside, will weigh about 99 lbs. From this, the weight of any balloon structure may be obtained, taking care to add the weight of the sills, which, if of pine, spruce or hemlock, will weigh about 27 lbs. to the cubic foot.

The weight of ordinary floors with 2" × 10" joists, 1 inch flooring, and plastered ceiling under, will average per square of 100 feet, about 1000 pounds, if all the material is dry.

Brick walls are generally estimated by the number of bricks they contain, or by the 1000. Ordinary bricks, according to Trantwine, weigh about two tons per thousand, and a thousand of pressed bricks weigh two-and-a-quarter tons, therefore it is only necessary to know how many thousand bricks there are in a wall to be able to tell how much that wall weighs.

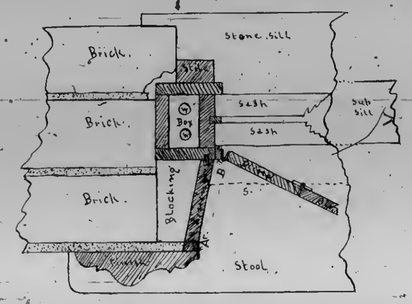
Of course, the weight of bricks will vary some little, owing to the difference in the clays of which they are made; but the little variation will not affect the figures given to any serious extent. To lay 1000 bricks requires 22½ cubic feet of mortar, and one cubic foot of mortar weighs 110 pounds, so that we find that one thousand bricks built up with good mortar weighs altogether 6475 pounds, or nearly three-and-a-quarter tons of twenty hundreds each. To this weight must be added the inside "rendering," furring, lathing and plastering.

The weight of stone-work differs with each kind of stone used. Sandstones weigh about 132 lbs. to the cubic foot, while limestones weigh 175, and some kinds of granite over 200 lbs. In laying random coursed rough quarried limestones, with good lime mortar and spalls, a solid cubic foot in the wall will weigh 190 lbs., so that a cord of stone, measured in the wall at 100 cubic feet, will weigh nineteen thousand lbs. A cord of sandstone in the wall will weigh about 1000 lbs. less, while a cord of boulders or "hard-heads," whole or broken, will weigh over 21,000 pounds.

These replies cover, to the fullest extent, all the questions asked by our Montreal correspondent.

"W. S. K.," Belleville, Ont., writes: "In reply to "A Carpenter in Distress," in one of your recent issues, I send herewith a rough sketch of an economic way of preparing a window in a brick wall for inside blinds. By examining the sketch, the enquirer can see how the work is finished. The distance from A to B should be a little more than one-quarter of the width of the opening; this will permit the blinds to fit back snug without projecting into the room. The lining may be pannelled if the extra expense is no object, but when strict economy is the order of the day a plain finish may be adopted, or the lining may be formed of matched and beaded stuff.

If it is desired to run the splayed jamb lining down to the floor, this may be accomplished by putting in a stool that will project into the room no further than where the dotted lines show at S. This will make a recess in the wall under the window, which should be filled up to the stool with pannel work. If the splayed jamb lining is pannelled, a rail should be framed in at



the point where the stool S is situated, as it is not likely that the stiles would be wide enough to receive the projection of the stool.

The sketch, and this description, will, I think, relieve your enquirer from his difficulty. Of course there are many other methods of getting over this difficulty, but I know of none that answers the purpose at so small an outlay, but if any of your readers know of a better method costing no more, I, along with your enquirer, I am sure, will be glad to hear of it.

MONTREAL MASTER PLUMBERS.

The Master Plumbers' Association, of Montreal, met on Thursday, the 3rd inst., in their rooms "Salle St. Joseph," corner of Sanguinet and St. Catherine streets. The Association has accomplished much valuable work, considering its recent formation. The membership roll contains the names of ninety members. Much attention has been devoted to sanitary matters, and good results are likely to be achieved in this direction.

The election of officers was proceeded with after the usual preliminaries, and resulted as follows: Honorary President, John Date; President, P. J. Carroll; 1st Vice-President, Alp. Champagne; 2nd Vice-President, D. Sexton; 3rd Vice-President; Thos. Moll; Secretary, J. W. Harris; French Corresponding Secretary, C. E. Thibault; English Corresponding Secretary, G. C. Denman; Financial Secretary, J. A. Sadler; Treasurer, Jos. Obeau. The following were chosen as chairmen of the various committees: Sanitary, H. Paddon; Arbitration, Joseph Lamarche; Auditing, E. C. Mount; Legislative, P. C. Ogilvie; Apprentice, D. Gordon.

MR. P. J. CARROLL.

Mr. P. J. Carroll, the new president, whose portrait we present, is one of the most successful and popular men in the trade in Montreal. He has risen from the ranks to a position of prominence in his chosen line, and at present enjoys the confidence of his confreres and the public alike.

Mr. Carroll was born in Ireland 37 years ago, and at the age of 4 years was brought to Montreal by his parents, where he has since continuously resided. He was educated at old St. Laurence school, and at an early age entered into his apprenticeship under the direction of his elder brother, who had already obtained a foremost position in the trade, being at this time foreman in the shop of John Burns & Co. Mr. Carroll remained at the plumbing and steam-fitting trade with Messrs. Burns & Co. for 11 years, when he and his brother decided to embark in the business on their own account. Twelve years ago they founded the firm of Carroll Bros., but at present Mr. P. J. Carroll is the only member of the firm, his brother having died two years after the formation of the partnership. The business has prospered, and at present is one of the leading shops in the trade.

MR. P. J. CARROLL.

Mr. Carroll is a modest, unassuming gentleman, and combines with these qualities much executive ability, sound judgment and a wonderful tenacity of purpose, and under his direction we predict a most successful year for the Master Plumbers' Association of Montreal. He is to be congratulated on being unanimously called by his confreres to fill the most honorable position in their gift, and in electing him to this office they have done honor to themselves and have recognized and rewarded merit.

MEETING OF SANITARY COMMITTEE.

A meeting of the Sanitary Committee of the Dominion Association of Master Plumbers was held at the rooms of the local association of master plumbers in London on the 3rd and 4th of December last.

The members of the Sanitary Committee are Messrs. W. H. Heard, London; M. Birch, Kingston; Walter Mashinter, Toronto; Adam Hall, Peterboro'; Adam Clark, Hamilton.

The question of uniformity of sanitary by-laws throughout the Dominion was thoroughly discussed. The advisability and necessity of a Dominion law governing sanitary construction was carefully considered, and the conclusion arrived at by the committee was that, in the interest of the public, as well as the trade, there should be a law embracing the entire Dominion, and the committee will so recommend. It was thought by some that perhaps it would be best to recommend that action be taken in Ontario as a preliminary step to getting a Dominion act. It was the opinion of the committee that the enforcement of the law should rest with the board of health, and that each local board of health should have at least one plumber as a member.

The inspection by-law was also carefully considered, and an effort made to remedy some of the defects in existing by-laws.

The committee were also strongly in favor of the appointment, in each town and city of sufficient size, of a board of plumbing examiners, whose duty it will be to advise the council or board of health on all matters appertaining to sanitary apparatus and construction, and to suggest such changes as may be necessary from time to time to keep by-laws up to date. Inspectors should be under the control of this board of plumbing examiners, who would also decide and adjust disputes arising from the operation of the by-law. The constitution of this board was also considered. This matter will come up at a subsequent meeting of the committee.

Considerable time was taken up in discussing a model specification, to eliminate as far as possible objectionable features to existing by-laws, said specification to be subject to such changes as the most modern practice and experience dictates, full consideration being given to the proposed by-law in London "To Secure the Better Sanitary Condition of Buildings."

A committee was appointed to confer with the local board of health, and it is hoped that their labors will materially aid the authorities in arriving at a satisfactory enactment.

A LONDON PLUMBING ESTABLISHMENT.

A description of the plumbing establishment of Messrs. Smith Bros., London, Ont., appears in a local paper, from which we take the following: The business was established ten years ago by William and John Smith, but since the death of the latter two years ago Mr. Wm. Smith has conducted the business under the former name. He is the only plumber in the Dominion holding medals for mechanical ability, which medals are on exhibition at his shop one being of bronze and two each of silver and gold.

The growth of the business has been such that the present premises, though large, have become too small, and at the beginning of the new year a move will be made to 265 Dundas street, where there will be three floors, 32x75 ft., instead of two floors, 16x75 ft., as at present. The show room in the rear, where plumbing apparatus will be exhibited in working order, will be the finest west of Toronto, and an undoubted credit to the city.

Mr. Smith is the inventor of an apparatus for testing plumbing work, to prove whether the sanitary part of the plumbing in buildings is perfect or not. To show the standing he enjoys among those of his own craft it may be mentioned that he is the vice-president for Ontario of the Plumbers' Association of the Dominion.

In modest houses, where repapering cannot be done often, all papers should be of the quiet sort, with indistinct figures and good, clean, clear tones of colour. Any decided design, such as stripes, or formal, conventional figures, is apt to pall upon the eye before the paper can be renewed.

PROPOSED LEGISLATION AFFECTING PLUMBING AND DRAINAGE.

We are permitted to print below a copy of a proposed act which has been drafted by Mr. W. J. Burroughes, of Toronto, the object of which is to secure the registration of master plumbers and the supervision of plumbing and drainage in the cities of Ontario. The bill will in all probability be presented at the next session of the Ontario Legislature, when it is hoped to secure its adoption. Mr. Burroughes has not yet submitted the bill to the city authorities or to the Ontario officers of the Master Plumbers' Association, and it is not unlikely that some slight amendments will be made thereto before presentation.

A perusal of the different sections leads one to the conviction that the desired legislation will be favorably received, inasmuch as the objects sought are largely for the protection of the general public, who suffer as the result of defective plumbing and drainage. Under the present conditions any person is permitted to undertake plumbing work without producing proof of qualification, and consequently much inferior plumbing is allowed to be placed in buildings, which, besides endangering the lives of the inhabitants, sooner or later requires to be renewed at a large expense to the owner.

The proposed bill is entitled "An Act to Secure the Registration of Plumbers and the Supervision of Plumbing and Drainage in the Cities in the Province of Ontario," and reads as follows:

1. Within ninety days after the passage of this act it shall be the duty of the mayor of each of the cities of this province to appoint a board for the examination of plumbers for such city, where such board shall act, to be known as the "examining and supervising board of plumbers and plumbing." Such board shall consist of five persons, of whom two shall be employing or master plumbers of not less than ten years' experience in the business of plumbing, and one shall be a journeyman plumber of like experience, and the other members of said board shall be the chief inspector of plumbing and drainage of the board of health of such city, and the chief engineer having charge of sewers of said city; but in the event of there being no such officers in such city, then any two other officers having charge or supervision of the plumbing, drainage or sewerage, whom the mayor shall designate or appoint, or two members of the board of health of such city having like duties or acting in like capacities. The term of office of the master and journeymen plumbers first appointed under the provisions of this act shall be as follows:

One shall be appointed for one year, one for two years, and one for three years, their terms of office to expire respectively one two and three years from and after the thirty-first day of December of the year in which such appointments shall be made, and the mayor, in making the first appointments, shall for each one so appointed specify the duration of the term of office to which he makes said appointments respectively, and annually thereafter upon the expiration of the term of office of any such member of the board, his successor shall be appointed by the mayor for the term of three years or until a successor shall be appointed, and the mayor shall have power to fill any vacancy caused in such board of examiners by the death, removal, inability to act, resignation or removal from the city of any member thereof, and such appointment shall be for the unexpired term.

Such chief inspector of plumbing and drainage, and such chief engineer in charge of sewers or the officers holding equivalent positions or acting in like capacities designated or appointed by the mayor as herein provided, shall be deemed to be also ex-officio members of such examining board, and when they shall cease to hold the offices by reason or on account of which they were so designated or appointed, their successors shall act on the examining board in their stead.

2. It shall be the duty of such ex-officio members of the board of examiners to discharge their duties as members of this board without compensation therefor. The master and journeymen plumbers serving as members of such board shall severally be paid at the rate of five dollars per day for each day's services when actually engaged in the performance of the duties pertaining to the office, but such compensation shall not exceed the sum of five dollars per month in cities of one hundred thousand inhabitants or less, nor the sum of ten dollars per month in cities having a population of over one hundred thousand and less than three hundred thousand.

3. All the members of such board shall be citizens and actual residents of the city in which they are appointed.

4. The several boards of examiners constituted under this act shall have power and it shall be their duty:

(1.) Meetings.—To meet at stated intervals in their respective cities; they shall also meet whenever the board of health of such city, or the mayor thereof, shall in writing request them so to do.

(2.) Examinations.—To have jurisdiction over and to examine all persons desiring or intending to engage in the trade, business or calling of plumbing as employing plumbers in the city in which such board shall be appointed, with the power of examining all persons applying for certificates of competency as such employing or master plumbers, or as inspectors of plumbing, to determine their fitness and qualifications for conducting the business of master plumbers or to act as inspectors of plumbing, and to issue certificates of competency to all such persons who shall have submitted to and passed a satisfactory examination before such board, and shall be by it determined to be qualified for conducting the business as employing or master plumbers or competent to act as inspectors of plumbing.

(3.) Plumbing Code.—To formulate, in conjunction with the local board of health of the city in which it shall act, a code of rules regulating the work of plumbing and drainage in such city, including the materials, workmanship, and manner of executing such work, and from time to time to add to, amend or alter the same.

(4.) Fees.—To charge and collect from each person applying for examination the sum of five dollars for each examination made by said board, and such moneys to be paid monthly to the treasurer of such city in which said board shall be appointed.

5. Any person desiring or intending to conduct the trade, business or calling of a plumber or of plumbing, in any of the cities of this province as employing or master plumber, shall be required to submit to an examination before such board of examiners as to his experience and qualifications in such trade, business or calling; and after the first day of March, eighteen hundred and ninety-seven, it shall not be lawful in any city of this province for any person to conduct such trade, business or calling, unless he shall have first obtained a certificate of competency from such board of the city in which he conducts, or proposes to conduct, such business.

6. On or before the first day of March, eighteen hundred and ninety-seven, every employing or master plumber carrying on his trade, business or calling in any of the cities of this province shall register his name and address at the office of the board of health of the city in which he shall conduct such business, under such rules and regulations as the respective boards of health of each of the cities of this province shall respectively prescribe, and thereupon he shall be entitled to receive a certificate of such registration, provided, however, that such employing or master plumber shall, at the time of applying for registration, hold a certificate of competency from an examining board; but such registration may be cancelled by such board of health for a violation of the rules and regulations for the plumbing and drainage of such city duly adopted and in force therein, after a hearing had before said board of health, and upon a prior notice of not less than ten days, stating the grounds of complaint and served upon the person charged with the violation of the aforesaid rules and regulations; but such revocation shall not be operative unless concurred in by a majority of the local board of examiners.

And after the first day of March, eighteen hundred and ninety-seven, it shall not be lawful for any person to engage in, or carry on the trade, business or calling of an employing or master plumber in any of the cities of this province unless his name and address shall have been registered as above provided.

7. Within sixty days after the organization of such examination board in any of the cities of this province, the local board of health, or the commissioner or commissioners of the board of health or the health department thereof, as the case may be, shall detail, designate, or appoint for the purposes of this act and the enforcement of the provisions thereof and the work of inspecting the plumbing and drainage of buildings, in said city, an inspector or inspectors of plumbing, subject, however, to the provisions or limitations of existing laws regulating the appointment of inspectors by such commissioner or commissioners or board or department of health of such city.

But all inspectors of plumbing so detailed, designated or appointed, and all inspectors of plumbing hereafter appointed, shall be practical plumbers not engaged directly or indirectly in the business of plumbing during the period of their appointment; and they shall be citizens and actual residents of the city in which they are appointed, and before entering upon the discharge of their duties as such inspectors each shall be required to obtain a certificate of competency from said examining board. They shall be entitled to receive compensation not exceeding five dollars per day for each day of actual service, to be fixed by the board, commissioner or department making such appointment.

8. The duties of the inspector or inspectors of plumbing appointed under the provisions of this act, in addition to the duties prescribed by law, and those which may be enjoined or required by the commissioner of health, the board of health or the health department of the city in which they shall be appointed, shall be, to inspect the construction and alteration of all plumbing work performed in such city subsequent to the passage of this act, and to report in writing the results of such inspection to the said commissioner of health, or the board of health department of their respective cities; they shall also report in like manner any person engaged in or carrying on the business of employing plumber without having the certificates hereinbefore mentioned.

9. All certificates of registration issued under the provisions of this act, and all licenses authorizing connection with street sewers or water mains, shall expire on the thirty-first day of December of the year in which they shall be issued, and may be renewed within thirty days preceding such expiration, such renewals to be for one year from the first day of January in each year.

10. Whenever any inspector or other person reports a violation of any of said rules and regulations for plumbing and drainage, or a deviation from any officially approved plans or specifications for plumbing and drainage filed with any board or department, the local board of health shall first serve a notice of violation thereof upon the master plumber doing the work, if a registered plumber. Such notice may be served personally or by mail, and if by mail it may be addressed to such master plumber at the address registered by him with the local health board; but the failure of a master plumber to register will relieve any board of health from the requirement of giving notice of violation. Unless the violation is removed within three days after the date of serving or mailing such notice, exclusive of the day of mailing or serving, the board of health may proceed according to law.

11. From and after the first day of March, eighteen hundred and ninety-seven, the plumbing and drainage of all buildings, both public and private, in each of the cities of this province, shall be executed in accordance with the rules and regulations adopted by the local board of examiners in conjunction with the board of health for plumbing and drainage; and all repairs and alterations in the plumbing and drainage of all buildings heretofore constructed shall also be executed in accordance with such rules and regulations, where the board of health shall have control, but this section shall not be construed to repeal any existing provisions of law requiring plans for the plumbing and drainage of new buildings to be filed with any local board of health and to be previously approved in writing by said board of health, and to be in accordance therewith, except that in case of any conflict between such plans and the rules and regulations of the board of examiners, the latter shall govern.

12. Each of such boards of examiners shall have power to procure suitable quarters for the transaction of business, to provide the necessary books and stationary, and to employ a clerk to keep such books and record the transactions of such board. The board of control and apportionment of the city of Toronto and the common council of all other cities, shall annually insert in their tax levy a sufficient sum to meet the expenditures incurred under the provisions of this act; and all expenses incurred by the several boards of examiners in the execution and performance of the duties imposed by this act shall be a charge on the respective cities, and shall be audited, levied, collected and paid in the same manner as other city charges are audited, levied, collected and paid.

13. Any person violating any of the provisions of this act, or any rules or regulations of the board of health, or of the board of examiners in any city regulating the plumbing and drainage of buildings of such city, shall be deemed guilty of a misdemeanor, and upon conviction, if a master plumber, shall, in addition, forfeit any certificate of competency or registration which he may hold under the provisions thereof.

14. After the passage of this act the commissioner of public works of any city, or the officer or officers acting in a like capacity in any of the cities of this province, and having charge of the sewers and water mains, shall not issue a license to anyone to connect with the sewers or with the water mains of such cities unless such person has obtained and shall produce a certificate of competency from the examining board of such city hereby created.

15. All acts or parts inconsistent with or repugnant to the provisions of this act are hereby repealed.

16. This act shall take effect immediately.

NATIONAL ASSOCIATION OF MASTER PLUMBERS.

The following is a copy of the resolutions adopted by the Dominion Association of Master Plumbers to confine the sale of plumbing supplies to those legitimately engaged in the trade:

Whereas, The manufacturers and wholesale dealers in plumbing material are selling to consumers, to our injury and detriment, placing us toward our customers in the light of extortionists, causing endless trouble; and

Whereas, The system of protecting us from this wrong which draws in its wake other wrongs, is ineffective, it is absolutely necessary to perfect such a system by united action which will remove these evils from which we have suffered for years; therefore be it

Resolved, That the members of this association confine the purchase of plumbing material to manufacturers and wholesale dealers who sell goods to master plumbers only, as defined in these resolutions;

Resolved, That this association shall keep a record of all journeymen and plumbers, who place in buildings plumbing material bought by consumers, of manufacturers or dealers;

Resolved, That a committee be appointed by this association in every province and county for the purpose of reporting to the proper officers at its head in the province, any violations of these resolutions;

Resolved, That these measures are just and necessary to our welfare, and a rigid enforcement is demanded;

Resolved, That this convention endorse the above, and are authorized to adopt a uniform system of protection for the trade over their entire jurisdiction;

Resolved, That it is not the intention of said resolutions to prevent the interchange of patented or any other plumbing material between manufacturers and wholesale dealers in such goods, or for the export trade, and that the interpretation of the above resolutions be left in the hands of the executive committee with power.

INTERPRETATION OF THE TERM "MASTER PLUMBER."

Resolved, That it is the sense of this convention that in the future the interpretation of the term "master plumber," as set forth in the above resolutions, to entitle him to purchase plumbing material, be construed to mean a master plumber who has an established or place of business and represents the industry of plumbing, and who has qualified under the dominion, provincial or local enactments regulating plumbing and plumbers, where such exist; or, where no license is required, an individual or firm with an established place of business and representing the industry of plumbing;

Resolved, That any manufacturer or dealer in plumbing material furnishing net prices, or any discount from list prices to others than master plumbers, either by themselves, employees, or agents, shall be considered as disapproving the above resolutions;

Resolved, That the supply houses doing a plumbing supply business, and contracting for plumbing work, shall be considered unjust competitors.

The following are exempt from the above resolutions:

The dominion and provincial governments, mines, and street railway companies.

Provincial and city institutions.

Railroad, gas, water and electric light companies only for such goods as are necessary for their respective lines of business.

The above resolutions apply to the whole Dominion of Canada.

v.8-9

arc
and

A NEW FLOORING MATERIAL.

THE name of papyrolith is given to a novelty in flooring material which has lately been invented by Otto Kraner of Chemnitz, the article being a special preparation of paper pulp, which is in the form of a dry powder; when mixed with water it may be spread like mortar over stone, cement or wood, where it dries quickly and may be smoothly planed, besides which it may be tinted almost any color, in this way adapting it for parquetry with variegated borders, or for panels and mosaics. Among the various advantages claimed by the inventor for the use of this product are freedom from crevices, deadening of noises and poor conduction of heat, also considerable elasticity, safety from fire and remarkable durability. It may be employed too, for wainscoting and other architectural purposes, as well as for flooring.

USEFUL HINTS.

"Double-boiled" oil is that which has reached a temperature great enough to scorch a feather when held in it, and reaching about 300 degrees C.

Yellow and orange chromes have a tendency to rapidly blacken, as in the case with white lead, when exposed to sulphur gases, or when mixed with pigments containing sulphur and arsenic sulphide.

A correspondent asks a European exchange: "How are old stones best treated which are covered with soot? They are to be painted with a light color." The answer was: "If the soot is from wood smoke, it is best removed by the use of caustic lye soda or calcined ashes (1 pound to 8 pints of rain-water); otherwise, by means of soap lye."

The only safe way to obtain a perfectly harmonious contrast in colours is to apply them, when mixed, to the actual position they are to occupy when the scheme of decoration is completed. A series of colours that may look well indeed when used in a dimly lighted room will often appear very objectionable when exposed to a brilliant light.

A very simple remedy to remove rain spots, or such caused by water soaking through ceilings, has been employed with good results. Take unslaked white lime, dilute with alcohol, and paint the spots with it. When the spots are dry—which ensues quickly, as the alcohol evaporates and the lime forms a sort of insulating layer one can proceed painting with size color, and the spots will not show through again.

The property which gives linseed oil its special value as a paint oil is that when exposed to the air it gradually becomes hard, and dries up, in doing which it takes from the atmosphere a large proportion of oxygen, forming a new compound of a resinous character, the properties of which have never been fully investigated. In this power of combining with oxygen, linseed is distinguished very markedly from other oils, which have little or no power of combining with oxygen.

A very pretty effect has been obtained in the hall of a Brooklyn residence by hanging the walls with an Empire pattern lincrusta, the ground work of which has been painted a dull blue green, while the wreaths and flambeaux that are repeated at regular intervals upon it have been picked out with a pale Nile green. The ceiling has been tinted a greenish white, and upon it a simple fresco border has been painted, repeating the Empire flambeaux in the corners. The old-fashioned wood work, classic in its design, and the white enamelled balusters with the polished mahogany handrail, harmonize very nicely with the decoration of the walls.

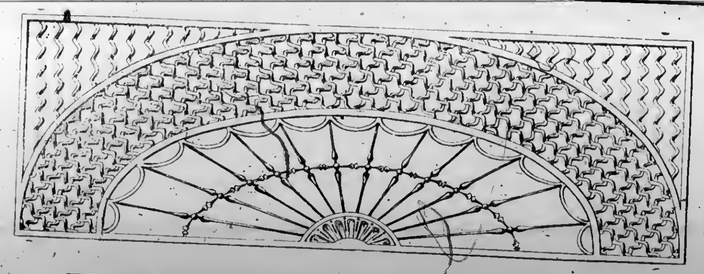
RECIPES FOR WATER-PROOF GLUE. — Water-proof glues, often used for pasting, but more frequently as a medium for colors, may be prepared in the following ways, according to the requirements of the case or the desire of the user: The glue is put in water till it is soft, and subsequently melted in linseed oil at moderate heat. This glue is neither affected by water nor by vapors. Dissolve a small quantity of sandarac and mastic in a little alcohol, and add a little turpentine. The solution is boiled in a kettle over the fire, and an equal quantity of a strong hot solution of glue and isinglass is added. Then filter through a cloth while hot. Water-proof glue may also be produced by the simple addition of bichromate of potash to the liquid glue solution, and subsequent exposure to the air. Another way is by mixing glue as usual, and then adding linseed oil in the proportion of 1 part oil to 8 parts glue. If it is desired that the mixture remain liquid, ½ ounce of nitric acid should be added to every pound of glue. This will also prevent the glue from souring.

The Council of Arts and Manufactures of Montreal, has appointed Mr. G. A. Monette, architect, Professor of Architecture of these classes.

The offices of the Prismatic Glass Co., of Toronto, have been removed to 65 Yonge St., where commodious show-rooms have also been fitted up.

Edward New has established an industry for the manufacture of fire-brick and fire-clay at Hamilton, Ont. The fire-brick has been tried in the west end pottery kilns, and is said to have proved a success. Mr. New has had the products patented.

A deputation of hardware merchants recently made request of the Tariff Commissioners that the classification of hardware for customs purposes be simplified. Builders' hardware, upholsterers' hardware and saddlery hardware are all under different duties, ranging from 20 per cent. to 35 per cent., and very much mixed. Workmen's tools are 35 per cent., builders' hardware 2½ per cent., tapes 25 per cent., picks 35 per cent., sledges and crowbars 30 per cent., adzes and axes 35 per cent. An ad valorem instead of a specific duty on building paper was suggested.



The Southampton Mfg. Co., Ltd.

MANUFACTURERS OF

MOORISH FRET WORK, SPINDLES, GRILLE,

TURNED AND TWISTED MOULDINGS, SPIRAL TURNINGS, BALLS AND SPINDLES NEWELS AND BALUSTERS

Send for Catalogue.

Southampton, Ontario, Canada.
